If the hand-camera be of the twin lens, or reflex, type, there will not be any difficulty in focussing the subjects up to the moment of exposure, but if the camera be focussed by means of the usual scale adjustment it will be found useful to have a focussing screen fitted to the camera, so that the lens may be sharply focussed upon some mark upon the stage, on or about the place the person will stand when the photograph is taken; if the whole of the stage is to be photographed it is advisable to focus upon a point about one yard beyond the footlights, in preference to depending upon the use of the focussing scale when using lenses at a very large aperture on account of the lack of depth of focus. This method of focussing demands the addition of some form of view-finder to the camera, and the writer prefers the direct vision type, so that the subject may be accurately centred upon the plate. The remaining items in the specification of this hand-camera may be arranged by the user to suit his convenience, but great care must be exercised in contriving that all the moving portions of the camera, and especially the shutter, should work silently, because a very slight noise in the theatre disturbs the spectators and interferes with their comfort.

Probably one of the most important items in this contribution is that which explains the preparation of the dry plates, which are treated so as to obtain the highest possible sensitiveness to artificial light. Some workers in this branch of photography prefer to use a high-speed ordinary plate. Dr. Grün has advocated the "Monarch" plate for this work, but the writer's experience is that a "ordinary" plate, however fast, can equal for such work by artificial light a plate bathed in orthochrome T solution in the manner about to be described. Practical tests are necessary to convince those who do not believe in more scientific methods. The writer has also measured the speed of the prepared plates, and found that, for candle-light, the speed varied from 500 to 550 H. and D., and when it is remembered that the greater proportion of the illumination in the theatre is of a yellowish nature, which factor is against obtaining the best results with a plate which is not sensitised for the brighter colours, the results are such as might be expected.

### Preparing the Bathed Plates.

The plates which are used by the writer are Mawson's "Electric" plate. Probably other brands may give equally good results, provided that they are a clean-working plate of medium speed, but of this the writer cannot speak from experience. It may be as well to mention that the writer has not been able to obtain greater speed by using a very fast plate—in fact, from his experiments, he came to the conclusion that, within reasonable limits, the actual speed of the plate before bathing did not influence the ultimate speed attained by this treatment, and therefore he is of the opinion that it is best to use a plate of medium speed.

To prepare the plates, a stock solution of orthochrome T dye is made by dissolving 1 gramme of orthochrome T dye in 1,000 c.c. of alcohol 90 per cent., or this stock solution may be purchased ready for use; it is rather expensive, but a small quantity will bathe a considerable number of plates, and will keep for an indefinite period. The bathing solution is made up as follows:—

Orthochrome T dye stock solution .....	4 cc.
Ammonia .880 .....	3 cc.
Distilled water .....	200 cc.

The addition of the ammonia interferes with the keeping quality of the bathed plates, but is necessary in order to obtain the highest sensitiveness. This solution is carefully filtered, and used at a temperature of 60 deg. F. to 65 deg. F. It must be made up as required, and as the solution can only be used once, to obtain the best results, some arrangement for bathing the plates must be contrived which will permit of the economical use of the solution;

Study under two focussed Arcs—Miss Ada Twibell.

probably the best arrangement is to place several plates in a large developing dish, and to flow the solution over the plates exactly similar to the operation of developing. The presence of air bells must be avoided, and the dish rocked for three minutes; at the expiration of this period the solution is poured off the plates, and they are then washed in running water for three minutes. Remembering that these bathed plates are extremely sensitive to yellowish light, great care must be exercised to guard against light fog, and they should be manipulated, as much as possible, in the dark. The prepared plates are dried, as rapidly as possible, in the dark. A drying cupboard will be found a great convenience, and in the absence of other special facilities will be really a necessity. Details of various patterns will be found in several of the photographic text-books, or they may be purchased at the leading supply houses.

It has already been mentioned that as these plates are prepared with an ammoniacal solution they will not keep, and it is the practice of the writer to bathe the required number of plates the day before they are required, and so a constant supply of perfectly fresh plates is obtained.

### The Practice of Theatrical Photography.

In the natural sequence of events the plates are now exposed in the theatre, and therefore it will not be out of place if a slight digression be made in favour of a description of what the writer has found to be the best methods to adopt whilst working in the theatre.

When it is necessary to include the whole of the stage in the photograph the best place to work from is, undoubtedly, the front of the dress circle. During a public performance the stand camera would be entirely out of place in such a position, and it will be futile to ask the manager for the necessary permission, but the writer has photographed on several occasions in this position, when he was using the hand-camera, without abnormally disturbing the audience. It has already been mentioned that it is essential that the photographer should avoid disturbing the audience, and drawing their attention, and probably the best method to adopt in circumventing this ordeal is to wait until the public are settled in the enjoyment of the entertainment, and then, at a suitable moment, walk quietly down one of the gangways, and sit upon the bottom step, where he will be nearly hidden from view. After a brief wait for five minutes, of masterful inactivity, the camera may be quietly lifted upon the ledge which runs round the front of the circle, and the subject focussed upon the screen, which operation is followed by the exposure of the necessary number of plates. It is surprising how comfortable and secluded is this position, and a skilful operator will be able to obtain his negatives without attracting the attention of anyone, except the persons who sit on either side of him.

As a rule, it will be found that those scenes will produce the best prints which only include a few figures, and these should be well distributed over the stage, and not clustered in a group. The theatre management prefer that the photographs be taken with a huge crowd upon the stage, this bearing witness to the expensive character of the production, but as a matter of fact the presence of this crowd hides the scenery, obstructs the light, and casts heavy shadows, which generally mar the picture.

For the portrayal of single figures, or small groups of figures, it is advisable, for two reasons, to work from a position quite close to the stage. Here is obtained a considerable increase in the size of the figure upon the negative, and consequently it may be enlarged to better advantage, and with the production of less grain, than would be the case if the negative were taken from the front of the dress circle. Moreover, the nearer the subject is to the camera the shorter is the exposure when photographing by artificial light. This is, of course, quite contrary to the result obtained under daylight illumination, and is likely to at first somewhat puzzle the novice, but if he cares to experiment in this direction he will find this statement to be correct. For some time the writer was under the impression that the gain in illumination consequent upon the lessened distance between the camera and the subject was compensated by the automatic closing of the diaphragm, consequent upon the lens being racked out beyond its normal focus, but though there must be a loss of light by this rule,

the improved illumination obtained by the nearer approach of the subject was most marked.

For photographing single figures from the front of the house, the writer prefers to stand at the side of the stalls and to rest the camera against some convenient projecting portion of the building. An early opportunity is taken to actually focus the lens upon some particular portion of the stage, for it is never advisable to trust to focussing scales when using extremely rapid lenses, after which the plates may be exposed at pleasure.

### Varieties of Stage Lighting.

For the purposes of photography the stage lighting may be roughly divided into two classes, i.e., diffused lighting, when the whole of the stage is fairly equally flooded with light; and focussed arcs, or limes, when the light is concentrated by means of lenses upon some particular portion of the stage, or, more usually, upon the principal actor in the scene. Both of these effects are used independently and combined. The photographer must, however, be extremely careful to select an opportune moment for his exposure when photographing a subject lit by combined focussed and diffused lighting. This form of lighting gives some beautiful results, but is very liable to produce harsh negatives, in which the contrasts are so extreme as to be unprintable.

On the other hand the strong, bright lighting resulting from the use of focussed arcs only, produces some weirdly pretty effects, which photograph easily and well. The writer has thought that this form of lighting might be profitably employed in the studio by those who are in search of some novel effects in lighting.

Occasionally some pretty effects may be obtained by photographing from the "wings" on the stage, more especially when the figure is lit by focussed arcs. The writer has found that the best position to work from is seated upon a chair, so as to obtain a low point of view, on the O.P. side of the stage—that is, the right-hand side of the stage when the observer is looking at the auditorium. The reason for selecting the O.P. side of the stage is to avoid obstructing the officials in the execution of their duties. At the opposite, or prompt, side of the stage are the electricians, the stage manager, etc.

### A Ready Test for Intensity of Stage Lighting.

It is probably unnecessary to mention that photography ought not to be attempted unless the stage is lit with "white" light only. When the photographer has received a commission from the management, it is advisable, when making the necessary arrangements, to interview the electrician and stage manager, and arrange with them for the stage to be flooded with "all white light" when the photographs are being taken; in this way a considerable increase in the amount of light upon the stage may frequently be obtained. In the darkened theatre it is difficult to judge the amount of light there is upon the stage, for when the observer is watching the stage it appears to be brighter, by contrast with the darkened theatre, than it is actually. The writer overcame this difficulty by discovering that it is extremely easy to judge the volume of light upon the stage by observing the amount of light which is reflected from the stage into the auditorium; in this manner fluctuations in the light may be followed with ease.

It may be accepted as a general rule that the longest possible exposure should be given on all occasions, for it is unlikely that the photographer will ever meet with over-exposure, except under extreme conditions, as stage lighting usually gives heavy shadows.

### Development.

The development of these bathed plates is conducted in the usual manner, except that it is necessary, in order to obtain the best possible results from these negatives—which are usually badly under-exposed—to use the developer at a temperature of about 75 deg. F. It is doubtful whether heating the developer in this manner increases the speed of the plate, but it certainly gives a better result than when the developer is used at the normal temperature, even if development be prolonged so as to compensate for the increase in the velocity of development due to the use of warm materials. The writer is inclined towards the opinion that this phenomenon may be due to the light action being largely confined to the curve of under-exposure, which, according to Mr. Kenneth Mees, under prolonged

development gives an apparent increase in the speed of the plate. It is the practice of the writer to first warm the developing dishes by filling them with water heated to 75 deg. F., which is allowed to remain in the dishes until they are thoroughly warmed. The developer is then emptied out of the dishes, into which are placed the exposed plates, the developer, also heated to 75 deg. F., is poured over the plates, and the dish covered and rocked for five minutes, and sometimes longer: it depends altogether upon the character of the negative. The plates are fixed in the usual way.

Most of the organic developers will probably give equally good results, but it is necessary to use them without the addition of any restrainer, or restrainer, and at their maximum strength, so that when they are used at the stated temperature a slight fog appears over the whole of the plate; by this it is known that the whole effect produced by the action of light upon the plate is utilised. The advantage of using some of the developers at this strength and temperature is that they make the negative extremely "grainy," so much so, in fact, as to practically prohibit their use for enlarging purposes. For instance, the writer formerly used the H. and D. standard pyro-soda formula for developing these plates, and with it a most pronounced grain was obtained. After some experiments the writer found that edinol gave a nice negative, fairly free from grain, which will bear enlarging up to five or six diameters. In such cases the plates were of the same brand, and prepared in the same manner, so that it is quite evident that the size of the grain in some negatives is not entirely due to the lack of quality in the plate, but may be caused by the developer. Mr. S. E. Sheppard has also commented upon this phenomenon.

The formula which the writer is at present using is as follows:—

Sodium sulphite .....	5 oz. avoirdupois.
Edinol .....	96 grains.
Sodium carbonate cryst. ....	2 oz. avoirdupois.
Water .....	20 oz. fluid.

It is a one-solution developer, and is ready for use. The writer has not tested its keeping qualities, but his experience is that it may be used two or three weeks after manufacture.

### Making the Best of the Negative.

The negative will be found to be very thin—in fact, most operators would consider them hopeless, and unworthy of further consideration. Occasionally a fair print may be obtained from the original negative upon Velox or other gaslight paper which is prepared to give contrasty effects, but as a rule it will be found necessary to enlarge the picture out of the negative by making a hard transparency on a photo-mechanical plate in the camera, taking the opportunity to enlarge the picture about two diameters, and from this sensitive produce an enlarged negative in the camera; by exercising the precaution of obtaining as much contrast as is possible in the original negative and printing from it upon gaslight paper, the contrast in the final print will be all, if not more, than is required.

It is rather curious that the original negatives usually possess plenty of detail, though they are woefully deficient in contrast, so that the final print, obtained in the manner described, is not of such poor quality as might be expected. The prints which illustrate this article are produced in the above-described manner, but they have not been worked up by hand, and are only such as have been obtained in the course of experimental work. So that it will readily be seen that an artist, working upon one of the prints as a basis, could speedily produce a capital production, possessing that photographic quality which is demanded by the public.

For "rush" work, undertaken for the illustrated newspapers, probably the best course of procedure will be to make an enlarged half-toned collodion transparency from the original negative, and from this try to make an enlarged half-tone negative, also by the wet collodion process. The half-tone block may thus be produced, from a negative taken in the evening, in time to print for publication in the next morning's newspaper, for the coarse grain of the newspaper block obviates the necessity for retouching the print.

The discovery of means by which much greater sensitiveness than at present obtainable may be conferred upon photographic plates may, at any time, make the production of theatrical negatives a comparatively easy matter, but in the meanwhile it is believed that the

methods herein described will produce the best results obtainable under these trying circumstances.

The writer desires to express his indebtedness and thanks to Mr. F. C. Sutcliffe, of the Tyne Theatre, and Mr. W. Boardman, of the Pavilion Theatre, Newcastle-upon-Tyne, for their courtesy and kindness in providing the opportunity for experimental exposures within their theatres.

ARTHUR PAYNE, F.R.P.S.

### NOTE ON THE ILLUSTRATIONS.

The whole of the reproductions are from negatives taken, upon Mawson's "Electric" plates bathed with orthochrome T solution, during the public performances; only the ordinary stage lighting was used, the exposures being in all cases the same, i.e., about one-tenth second at  $f/3.6$ .

### THE LATE MR. GUARDIA.

OUR brief announcement last week of the death of Mr. Guardia having been made within a few hours of the intelligence reaching us, we may allow ourselves to supplement it with some notes on the deceased gentleman, who either by name or personally was known to large numbers of our readers. Mr. Guardia was a Spaniard by birth, but had been a naturalised Englishman for more than 25 years. His introduction to photography was obtained as an amateur at a time when any form of camera other than that employed on a stand was scoffed at or disparaged in comparison with the more cumbersome and unwieldy instrument. Mr. Guardia's photographic career was marked by his thorough advocacy of the hand camera as capable of everything which might be desired in photography and infinitely the superior of the stand camera, from the tourists' standpoint. His own ideas at that time in camera construction brought him into relations with Mr. A. S. Newman, a mechanic, as everybody now knows, of the highest order, and one, too, able to adapt his grasp of mechanical construction to the many refinements which go to make the perfect camera. The two men associated themselves in partnership about seventeen years ago, since which time connoisseurs of cameras have discovered what their workshops were capable of and how the letters "N and G" were a hall-mark of quality in design and workmanship. While on this topic, we may quote a letter received by ourselves last week as voicing the opinions of many others. Our correspondent, Mr. Horace W. Nicholls, writes from the Royal Colonial Institute, Northumberland Avenue, under date June 29:—

"In the current issue of the 'Sphere,' under a photograph of Boulter's Lock, the editor is good enough to make some kind remarks about the work I did during the South African War. It is gratifying at all times to know that one's work is appreciated, but I cannot pass it at the present juncture without saying that I feel I owed any success to the poor fellow who is to be buried to-morrow. I speak of Mr. J. Guardia, of the firm of Newman and Guardia, who designed and made the instrument I used during the campaign, and in which I was able to place such absolute reliance. All earnest workers in photography know the value of being able to do this, and I feel that the photographic world has suffered a severe loss by the death of one who would have nothing to do with anything that was not of the very best."

Mr. Guardia, who leaves a widow and two children, was buried in the Sheen and Mortlake Cemetery on Saturday last.

THE Berlin Exhibition.—The Preussisches Abgeordnetenhaus, in Berlin, is at present occupied by the photographic exhibition brought together by the Society for the Advancement of Photography (Verein zur Förderung der Photographie). The Royal Photographic Society has sent a collection of examples of pictorial photography.

HAROLD E. BRIGHTMAN, photographer, late of 39, Colston Street, Bristol, appeared for his public examination at the Bristol Bankruptcy Court on Friday before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £373, and assets estimated to produce £45. Mr. F. Richardson appeared for the debtor. Bad trade in the last two years was the cause of failure. His work was chiefly for trade advertising purposes. The examination was adjourned to July 27.

## Photo-Mechanical Notes.

### Zinc Plates for Collotype.

FRITZ HANSEN points out in the current number of the "Zeitschrift für Reproduktionstechnik" that attempts to use zinc plates instead of glass for collotype are really older than the use of glass itself. The reason why they have not been generally adopted is that the zinc reacts with the bichromate, and renders the whole of the gelatine insoluble. In the earlier experiments, too, the zinc was very impure, which also gave rise to other troubles. In order to use zinc plates they must undergo preliminary treatment, which consists in giving them a thin film of zinc chromate, and isolating this from the sensitised gelatine by a film of plain gelatine. A highly polished zinc plate should be covered with a 4 per cent. solution of chromic acid, and left till a perfectly uniform yellowish film of zinc chromate is formed. The plate should then be well washed and coated with a 5 per cent. solution of gelatine, a levelling stand and drying cupboard being used. The plate is then ready for coating with bichromated gelatine in the usual way.

In the early days of the use of zinc plates it was nearly always found that after two or three days dark spots made their appearance on the printing plates, and that these took the ink. The spots were caused by impurities in the zinc, and it was usual to apply salts of sorrel to remove them, but they appeared in such numbers that this treatment was useless. With the pure zinc as now made these spots are no longer met with, and the author strongly recommends every collotype worker to try the pure zinc plates instead of the fragile glass.

### Grained Photo-Mechanical Transfers.

Robert Sands, of Sydney, has taken out a patent for making transfers. The permanency of the grain is obtained by rolling the grain obtained by inking the surface of the transfer paper, and the rollers may also be covered with a stiff ink which only adheres to the highest parts of the photo-lithographic relief. The regulation of the grain is attained by varying the pressure. For small sizes paper can be used, but for larger sizes, or when accurate register is required, then sheets of celluloid or thin metal can be used.

The transfer gelatine, according to "Freie Künste," is made somewhat as follows:—300 parts of Nelson's gelatine are melted in from 1,500 to 2,000 parts of water; the quantity of water determines the fineness of the grain. To the warm gelatine solution are added 1 to 3 parts of ordinary alum in 300 parts of water, and the mixture filtered. After coating the transfer paper with this solution, sensitising with bichromate and drying, the paper is laid face up on one of the well-known inking-up boards, and rolled up with a cloth roller and stiff transfer ink. This is where the patent comes in, namely, the mechanical action of the pressure rollers on the grain. A hard, smooth printing roller is rolled for about a minute over the sheet till the grain appears matt; light pressure gives a fine grain, and vice versa. The pulls are now made in the ordinary way, each inked up with its own colour, developed under water, dried, and transferred to metal or stone. The process should be of special value for broad work, such as posters, as the high lights keep clean and the lines are sharp.

### "Electro-Printing."

According to "Freie Künste," Max Ullmann, of Zwickau, has discovered a new process to which he has given the above name, by means of which by mere contact of any original with a specially prepared plate, which is later used as the printing plate, any number of identical copies may be obtained. Coloured originals, pen-and-ink or pencil drawings, may by this process be absolutely faithfully reproduced. The prints are said to be staple to light and the atmosphere, and the process ought to be specially valuable for record work if the above statements are true.

## Patent News.

*Process patents—applications and specifications—are treated "Photo Mechanical Notes."*

The following applications have been made for Patents from June 18 to 23.

ROCKING DISHES.—No. 14,002. Improved rocking bath or tray for photographic or other purposes. John Tennant Grundy and Herbert Alban Dolby, 6, Rye Hill, Newcastle-upon-Tyne.

LENSES.—No. 14,168. Improvements in photographic lenses. Stephen Drummond Chalmers and Clara Chalmers, 8, Quality Court, London, E.C.

PIGMENT PRINTS.—No. 14,435. Improvement in photographic pigment paper. A. G. Bloxham, Birkbeck Bank Chambers, London, for the Neue Photographische Gesellschaft, Germany.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

FLASHLIGHTS.—No. 24,875, 1905. The invention relates to Patent No. 27,268, 1904, by the same inventor (B. J. P. Feb. 17, 1900, page 131), in which substances are added to a flashlight mixture to colour the flame suitably for orthochromatic photography; this coloured illumination taking the place of a screen or light filter for the plate. In the present specification two claims are made:—(1) Process for the simplified correction of the chemical effect of the spectrum for photographic purposes by means of coloured illumination of the object to be photographed with the aid of the process, described in the Letters Patent No. 27,268 of 1904, for the manufacture of smokeless, non-explosive slow burning or flashlight powders, characterised especially by the burning of powders producing light of different colour and mixed in the proportion of their various correcting effects. (2) Process characterised in that the powders corresponding to the composite colours are burned in form of sticks in proportion to their single correcting effects and combined in one or several complex cartridges which are consumed wholly by the fire themselves. Dr. Gottlieb Krebs, 120, Sprengelstraße, Offenbach-on-Maine.

THREE-COLOUR SCREENS.—No. 1938, 1906. The invention consists in a modification of the process for the preparation of three-colour screens for colour photography of the kind set forth in British Patent Application No. 19202 of 22nd September, 1905, in which thin transparent sheets of celluloid or other suitable material are prepared in the three principal colours and these sheets are cemented one upon another in uniform sequence of the colour until the accumulation of the single layer gives a sufficiently thick block for transverse sectioning. Robert Krayn, 24, Marien Strasse, Berlin.

## New Books.

THE middle of June seems a little late for the appearance of a magazine dated December, 1905, yet we nevertheless welcome the issue of another number of "The Photo-Minature" (Dawbarn and Ward, 6d.). It is the seventy-fifth of the series, and deals with bromide printing and enlarging. And yet, again, we are disappointed to find that the little volume hardly brings up to date our present practice of bromide, at any rate as far as this country is concerned. We can find only a few lines on modern methods of sepia toning, whilst a considerable space is allotted to the debatable uranium processes. The chiefly interesting chapter is that on the preparation of bromide paper and bromide linen, which comes from the pen of that versatile American worker, Mr. A. J. Jarmann.

A fourth and revised edition of "Chemistry for Photographers" by Chas. F. Townsend, F.C.S., F.R.P.S., has been issued by Messrs. Dawbarn and Ward, in the style of their popular series of still-life

annuals of which "Figures, Facts and Formulae" is one among a dozen well-edited textbooks.

Still another series of beginners' books commences its appearance with the issue of two small handbooks on "Correct Exposure" and "Correct Development" by the Rev. F. C. Lambert, M.A., Nos. 1 and 2 of "The Practical Photographers' Pocket Library," which deal succinctly and with commendable illustration with the elementary problems of the two essential operations in photography. The text-book of development leads the beginner to the "factorial" system, at the onset. These latest and most excellently produced handbooks are obtainable at the price of sixpence each from photographic dealers, and from the publishers, Messrs. G. B. Stoughton.

We have received the first issue of "Science and Technology," a monthly journal for teachers and students, edited by Mr. Oliver Dawson, and published at 254A, High Holborn, W.C. The issue contains an article by Dr. J. H. Smith and Dr. W. Merckens on "Making Photographic Prints in Natural Colours."

New Apparatus, &c.

The No. 4 A Folding Kodak. Sold by Kodak, Limited, 59-61, Clerkenwell Road, London, E.C.

It was to be expected that the Kodak Company would eventually add to their series of folding cameras one taking the popular half-plate size of picture. The No. 3 A (postcard) instrument was a step in the direction; the No. 4 A before us completes the series of folding cameras from the smallest to the largest, for half-plate marks the limit beyond which the practically useful hand-camera may not go. Considerations of depth, when the focal length of the lens is over 8 in. or 9 in., step in to arrest the development of the hand-camera into the larger sizes, even were many users to be found favourably disposed towards such necessarily larger and heavier cameras. In the No. 4 A bulk and weight are such as to withhold the title "pocket camera," yet it is carried very easily by its sling handle, much more so, in fact, than many box cameras

taking a picture one-half the size. In form and fittings it is modelled almost exactly on the No. 3 F.P.K., although it embodies one or two of the later improvements which the Kodak Company have made in their cameras. For example, the rising front has a rack and pinion movement for focussing. In addition to the usual scale there is the automatic device by which the front may be extended instantly to one of seven positions, representing sharp

forms of objects at 8, 10, 15, 20, 25, 50, or 100 feet. The metal parts are aluminium, the covering is fine seal grain leather, and as a whole and in detail the instrument is handsomely and strongly made. Its price is £7 7s.

The "Adhero" Dry Mounting Machine. Sold by the Adhesive Dry Mounting Company, Limited, 27-28, Fetter Lane, London, E.C.

This machine is placed on the market for the amateur worker. The company have several machines specially designed with a view to professional work, but in the present machine they offer for 25s. a complete outfit, by which an amateur can dry-mount prints up to whole-plate in size. The set includes the press, thermometer, spirit lamp, fixing-iron, two mounting covers, and a grey mounting board. The machine, as will be seen from the drawing, works by the operation of an eccentric cam, and communicates an open pressure quickly and without any mechanism which can become deranged. Of the process itself it is unnecessary for us to speak in terms of commendation. The method of attaching the print

to its mount by a solid and insulating "tissue" of lac substance is not likely to be improved upon, providing, as it does, the absolute flatness of the print on the thinnest mount, the perfect adherence of the two, and the protection of the print from any deleterious constituents of the mounting board. The only drawback to the process has hitherto been the very considerable outlay for a proper press. This obstacle the company have now removed in the small press before us, and in a larger one, for professionals, sold at £2 10s. These, we understand, are not the only reductions to be made in the execution of the plans which the company are following out, whereby the advantages of dry-mounting may be able to make a forcible appeal to photographers not as a perfectionist's method, but on economic grounds. A circular of the company's, to be obtained at 27, Fetter Lane, will show the very simple and expeditious procedure in employing the press and tissues.

MESSRS. W. BUTCHER AND SONS, Camera House, Farringdon Avenue, E.C., have introduced a very handy form of graduate, in which the lettering is clear glass on a dark ground, and thus very

easily seen in the dark room. The set of these measures (1, 4, and 10 ounces) is sent out, securely packed in cardboard case, at 2s., and the separate measures are obtainable for 6d., 7d., and 11d. respectively.

## New Materials.

The S.D. (Simple Development) Plate. Made by Marion and Co., Limited, 22-23, Soho Square, London, W.

This new plate, with self-contained developer, resembles, so far as its mode of employment is concerned, the "Amauto" plate of Ilford, Limited, reviewed not long ago in these columns. There may be, and probably are, differences in manufacture which sharply distinguish the two products, and, indeed, the sensitometric data which we give below prove that the two plates are quite distinct in their properties. But in general the "S.D." plate is on the lines of the "Amauto." The developing solution, or, rather, the energising solution which brings the developer contained in the plate into action consists of four ounces of carbonate of soda in a pint of water. In this the image appears immediately, almost in such a way as to suggest over-exposure. But on continuing development for from five to ten minutes, the plate builds up density, and proves itself capable of producing an excellent negative. Although prepared for automatic development, the plate may nevertheless be treated to remedy errors in exposure by prolonging the time of development in the case of over-exposures and adopting the same course, but in a much weaker solution of soda carbonate, when the exposure has been undertimed. The former, as with ordinary plates, is a more successful process than the latter, but both may be applied with advantage to the "simple-developing" plates.

The nature of the plates naturally precludes the determination of the full number of factors which sensitometrically describe a plate, but the following figures from determinations by Mr. S. E. Sheppard, B.Sc., may be given:—

Inertia, .25.

$\gamma_{\infty}$  (measuring the maximum contrast obtainable), 1.19.

Opacity to light,  $-4,300 \lambda = 18$ .

The plates are placed on the market by Messrs. Marion and Co. at the price of 2s. per dozen, quarter-plate size.

The Birmingham Photographic Company, Ltd., Stechford, inform us they are issuing a modification of their bromide paper as the result of several improvements in manufacture made during the past year. The present paper, to judge from the sample sent us, is in every way an excellent bromide.

## Correspondence.

\**\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**\* We do not undertake responsibility for the opinions expressed by our correspondents*

### "PHOTO-COPY" PROCESSES.

To the Editors.

Gentlemen,—Re the note in "Journal," page 482, "New Photo-Copy Process," some of the statements in the above paragraphs are, I am sorry to say, quite contrary to fact: (1) Ferro-prussiate paper is more largely used than all the other photo-papers put together, and is still coming into more general use. One firm alone in the North coats upwards of five tons weekly. For cheapness there is nothing to touch it—a roll 30in. by 32ft. (110 grammes to square metre) being supplied to engineers (large users) at 10d. to 1s. per roll; thus a 40in. by 27in. print (a single one), costs a shade over 1d. The ferro rapid paper can also be produced at the rate of two every three minutes. This is much quicker than any other process—gallic, or black line, or sepia.

Regarding Mr. Shawcross's claim to the introduction of black line and sepia papers, the following facts speak for themselves:—

Black Line or Ink Process.—M. Poitevin described it in a communication, May, 1860, to the Société Française de Photographie, and later on it was perfected as a commercial article by M. Colas, who published several formulas so good that at the present day they are still the standard ones in some houses. As early as 1864 they were commercially sold in this country. In 1884 Mr. Shaw-

cross took out a patent for treating the above paper by brushing the gallic acid on to it (instead of using a gallic acid bath). Although this was granted a patent (8771), it was at the time as old as the hills. Several years previously there were similar papers sold here by French and German agents manufactured in their countries. I myself saw it manufactured both in France and Germany, and also in the States long previous to his patent, and the fact that several English firms put on the market a similar paper of their own, with any injunction tried for, clearly proved the patent was useless.

As to Mr. Shawcross's claim to sepia paper, this was invented by Arndt and Troost, Frankfort-on-Maine. I have not the number of the German patent, but it is some time previous to the English one. The number of the latter is No. 20,368, June 29, 1895 (BRITISH JOURNAL OF PHOTOGRAPHY, 1895, page 541, August 23).

The "graph" process now being exploited is simply a copy of a French process, which was worked in London some time before the present "inventor" brought his out, and is undoubtedly due to the invention of the Paris firm.—Yours truly,

MARGRAND.

P.S.—Marions made these papers in Paris long before Mr. Shawcross thought of them, and excellent they were.

[We are glad to publish our correspondent's letter, which doubtless describes the practice of large users of "photo-copy" papers. Other users of such papers have adopted the ferro-gallic process in preference to the blue paper, but our correspondent's statements, which we have confirmed in other quarters, fairly represents the present state of the whole trade in heliographic papers. Mr. Shawcross to whom we sent proof of the above letter writes as follows:—Eds. B. J. P.]

Replying to your correspondent's remarks, re black line and sepia process in reference to myself, from whom he would take the credit of having introduced "a process" at all, I would state as follows:—

I do not claim to be the originator of the gallic acid or ink black line process as such. It is true that Poitevin, followed by Colas and others, published formulæ which professed to give these results—but with a liquid developing bath only—before I even thought of them; but I do claim that my invention of the "single water bath process" of obtaining the same end by the mechanical device of the double sensitising of paper: (a) with a photo-sensitive chemical salt—in this case an organic salt of iron; (b) with the developer, gallic acid, so as to require only exposure to light and a bath of a solvent such as water to produce a copy, and for which my patent was granted in 1884, was new and original with me, and probably formed a strong and master patent.

At any rate I may state that never during the term of seven years, down to 1892 when I allowed my rights to lapse, did it ever come to my knowledge that any such paper was produced or offered by any firm in Europe; nor was it necessary for me, as your correspondent suggests, to issue any injunction to stop such infringement! In fact down to that date the "single bath process" was unknown on the market except through agents (Messrs. Poore, of Liverpool) appointed by myself.

Your correspondent states that it was sold in this country in 1864, that it is as old as the hills, that he saw it manufactured on the Continent and in America, all previous to the date of my patent. Is he sure of his facts, and can he name any firms in England who offered or made the article? I have probably as many facilities for knowing as he has, and it never came to my knowledge who probably at the time was much more interested. In 1884 no firm in England, and they were then limited in number, offered such a paper. Nay, right down to '90, when my patent rights lapsed, it was not offered. Shortly afterwards it was marketed here through foreign agents and subsequently manufactured by certain northern firms, who never had the grace, even if they knew, to acknowledge the source of the process which they preferred to call their own.

Again my process was brought under the notice of the Institution of Civil Engineers in a paper on "Heliography," by Mr. B. H. Thwaites, A.M.I.C.E., in 1886, when it was unknown to the profession and received no challenge as to originality and novelty.

Your correspondent is wrong with regard to M. Marion making this paper. I received a personal visit from that gentleman in Liver-

shortly after the date of my patent with a view to his taking it. At that time the process was quite new to him. With regard to my sepia process your correspondent must surely have considered the facts before him. Arndt and Troost, to whom he would give credit of this process, introduced it on the Continent in 1894, and according to your correspondent's statement, tented it in England in 1895. Now if he had taken the trouble to enquire he would have found that my patents for this identical process are dated; 1st in Paris in March 1889; 2nd in London in 1902, or a clear precedence of 5 years and 3 years respectively. These facts speak for themselves."

HENRY SHAWCROSS,  
Bach. Eng.

PHOTO-MICROGRAPHS OF MOLTEN MINERALS, ETC.

To the Editors.

Gentlemen,—In reference to the note on my paper at the Rome Congress I may say that the aim is to be able to determine with photographs the changes which crystals at a certain temperature are subject to, and also the formation of crystals out of molten, or melting, substances. This study is made with a microscope, specially designed for this purpose. It is so constructed that, between the object-holder and the objective—best a Petzval objective with about 55mm. focus, as one does not need any greater enlargement—small electrical oven is placed. The temperature in the oven can be regulated by a resistance apparatus. In the oven the substance to be photographed is placed in a small cup of quartz-glass. The temperature can reach 1,500deg. nearly; the photographic objective is placed in a cooling apparatus, so as not to get heated. The camera is erected over the ocular. Now the question is to be able to repeatedly photograph the molten substance at different temperatures, and not only when the temperature is rising, but also when it is falling. My first experiments with usual light did not succeed, and I have now begun to use plates, which are especially sensitive to red light. This on the advice of Mr. Proboscht. But the success was only partial, as was necessary to use a lighted field. At 1,205deg. nearly, only red light is sent out by the oven, which is easily constituted with an

course inconvenient, as during such a long time changes in the substance can easily take place, which would spoil the photograph. The photographs I have taken between 1,200-1,400deg. have generally succeeded very well, but this has not been the case with the lower temperatures between 1,000-1,100deg. The substance does not limit enough light, and the time of exposure is very long (over 3 minutes). The result is mostly an indistinct photograph.

The photographing itself, the focussing, etc., is, of course, not easy, as the oven sends out heat in all directions, but we can, at any rate at higher temperatures, obtain quite sharp and distinct photographs with usual Perutz plates. The difficulty is to reach as good a result even at 1,000deg.

The photograph here reproduced is taken at 1,250deg., and shows a molten gold-spun powder.—Yours truly,

C. DOELTER.

Graz, Austria.

THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—“Disgusted Assistant” is a bit mistaken in a few points in his letter. The “backyard studio” man may join the P.P.A. for one year; sometimes he does, and then we lead him out from his backyard and shake him cordially by the hand. The next year, however, when he finds that nothing very tangible appears by being a member, he forgets his subscription, and after a few months we mourn him as lost.

If, however, he stays in two years, you will find that there is usually a little grace in him after all. He begins to look up to his superiors for instruction, and opens up his lens to *f*/6 at least. After a member has paid his subscription four or five times there is little doubt but what he is an enlightened man, and one that would be quite able to pass any ordinary assistants' examination with ease.

No, “Disgusted,” the stickyback, the touter, the “3-for-2s. 6d.-cabinet” men, are not often with us. They cannot see that they can get anything out of the job, and so do not join; and I am glad they do not.

OTHELLO, M.P.P.A.

To the Editors.

Gentlemen,—I notice in your last week's issue a letter from “Disgusted Assistant.” Now, “Disgusted Assistant” throws rather at the P.P.A., which is a body I have due respect for.

The P.P.A., unfortunately, did not take the precaution to exclude from their ranks those who carry on cheap canvassing and cutting businesses, and I presume this is what “Disgusted Assistant” alludes to. Of course everybody who knows anything about the country generally knows that the membership of the P.P.A. includes cheap canvassing firms as well as those who have never been photographers from their youth, but have turned over from other vocations. Now, everyone has the right to do what they like, but what sticks in the assistants' throats is these men becoming members of the P.P.A. without even as much as being questioned as to their abilities. The assistants must go through an examination to prove their abilities, while these men can get through without the slightest trouble. This has always been a thorn in the side of the assistants, and if the P.P.A. altered this state of things I am sure the young men of standing and ability would come forth for the P.P.A. certificates.

It is in the assistants' power to do what the P.P.A. could not possibly do—that is, to help to stop the innumerable frauds which are perpetrated every week, and which are given every publicity by the Editor of our JOURNAL. “Disgusted Assistant,” like myself, often feels somewhat disgusted at things which occur in the profession, especially in the cheaper lines of photography. Ever since the world was set buzzing there have been sharps and flats, so long as the uneducated can be gulled by the tact and persuasive element of certain men travelling as canvassers, who expound with gushing tones that they are going to give something for nothing. These men cannot get a hearing at houses whose education and artistic merit is a little above the average, who at a glance can see that the work which is being pushed under their nose is enough to make the moon turn pale.

the spectral ocular, of course, not recommencing with the ordinary light, which must be cut off. At higher temperature the substance sends out more yellow light. The photographs have, so far, been best with a clear red filter. I have also experimented with yellow filters at these high temperatures, but the photographs did not become clear. On the advice of Prof. Eder I then tried to use orange filters; my experiments with these are not yet finished, but the amount of yellow light increases up to 1,500deg., I think that the orange filters will be found most suitable for the purpose. The disadvantage of the red filter is the long time of exposure; at a temperature over 1,300deg. 1½ minutes is sufficient, but thereunder an exposure of at least 2 minutes is necessary. This is of

Like every other big trade, the photographic profession ought to have an amalgamated society of photographic assistants, to be connected very closely with the P.P.A., and to work in the best of spirit and motives, and then perhaps we should see a change for the better. If the assistants would only take the trouble to warn people of the various travelling photographic frauds, they could help themselves and others to higher positions. I have always fought these various bad systems, with a good deal of success.

After this, I am hoping the P.P.A. will band with them the managers and assistants of every branch, so that they can be quickly in touch with any of these bad systems, which are generally seen first by the assistants.

One more point which I wish to touch upon is colour photography. I have been astounded at the poor reception it has received at the hands of our best and most able photographers; they seem to ignore it, and might advance it great steps, having the time and money. It seems to have been left to a few, who will eventually cage it up and make a company of it. Things have occurred like this before, and then we have had the wailing of the profession over spilt milk.—Yours, etc,

ANOTHER ASSISTANT.

#### To the Editors.

Gentlemen, — Your correspondent, "Disgusted Assistant," although writing rather wildly about the composition of the P.P.A., yet throws out a valuable suggestion which, if made use of, would probably result in much good being done.

It is that the gaining of P.P.A. certificates should depend, not, as heretofore, on the testimony of employers, but upon the passing of an examination. This is what is wanted. The testimony of employers is of a somewhat dubious value, because of the varied modes and standards of work in vogue throughout the country. But on examination, taking, as I presume it would, a very high standard, would offer a stimulus to the present trudging assistant, and be the means of raising his work to the highest possible level. Chemists, draughtsmen, etc., hold certificates obtained by examination. Why not photographers?—Yours faithfully,

1, Granby House, Llandrindod Wells, July 2, 1906.

ALB. PAGE.

#### A REMEDY FOR PLATINUM PRINTERS' CATARRH.

##### To the Editors.

Gentlemen,—Make a strip of book muslin (washed) about 17in. long and 6in. wide, and fold three times lengthways. When using platinotype paper, pass strip under nostrils and over the ears. Soak portion of strip under nostrils with olive oil, and keep well oiled. That is all, and is simple to put on and take off. Having been a great sufferer from "catarrh," I thought other sufferers would like to try this. I can now cut up quires of platinotype paper with my strip, and feel no ill-effects whatever; formerly, only to open tube was sufficient to start me sneezing, etc., for the whole day and evening.—Yours truly,

PLATINO.

[A number of letters on this subject appeared in our pages last year, and the general conclusion then arrived at was that a species of catarrh which is experienced in some few isolated cases on the use of platinum paper—is noticeable chiefly in the cases of persons hyper-sensitive to dust. The filter recommended by our correspondent has doubtless proved necessary and efficacious for himself, but we have no ground for believing that there is a general need for such measures.—Eds. B.J.P.]

#### A NOTE ON THE SENSITOMETRY OF PLATES.

##### To the Editors.

Gentlemen,—The letter from Mr. A. Payne on the determination of the development factor in your issue of June 15 illustrates a misunderstanding which has been brought to my notice before. I think it would be well if I put the crux of the mistake in the forefront of my argument. The constant, K, does not measure the

rapidity of development for different plates, if by this is understood the time taken to reach a definite—the same—factor  $\gamma$  save when the value of  $\gamma_{\infty}$  is the same. May I refer Mr. Payne and others interested in this question to two papers on the development factor ("Phot. Jour.," 1903, February and July), which contain the first exposition of the method of determining a plate's development properties brought forward by Mr. Mees and myself; or to the latter paper on the theory of the process ("Phot. Jour.," 1905), in which the subject is more fully discussed. It may be well to state the physical meaning of the constant, K, obtained by calculation. It is that fraction of the final density, or  $\gamma_{\infty}$ , which would be developed in unit time if all conditions remained the same throughout development—i.e., if the original amount of developable halide remained constant. The (total) rapidity of development depends both on K (the velocity-constant of development) and on  $\gamma_{\infty}$ . Thus, with two plates, one having a high K but low  $\gamma_{\infty}$ , and the other a low K and high  $\gamma_{\infty}$ , the values of the development factor reached in a given time may be much the same at one stage.

That Mr. Payne's experimental results do not clash with the formula given, but rather confirm it, when viewed correctly, the following comparison of the graphic and calculated values will show:—

TABLE 1.

Plate.	$\gamma_2 \gamma_1$	K	$\gamma_{\infty}$
1 .....	1.17 .....	.885 .....	1.31
2 .....	1.79 .....	.112 .....	4.17
3 .....	1.756 .....	.137 .....	3.02
4 .....	1.73 .....	.154 .....	2.72
5 .....	1.67 .....	.202 .....	3.06
6 .....	1.64 .....	.226 .....	3.34
7 .....	1.52 .....	.337 .....	2.76
8 .....	1.69 .....	.202 .....	3.07
9 .....	1.74 .....	.150 .....	4.06
10 .....	1.60 .....	.250 .....	2.46

The next table gives the values for  $t\gamma_s$  and  $t\gamma_{1s}$  obtained graphically by Mr. Payne and calculated from the special equation:—

TABLE 2.

Graphic.	$t\gamma_s$	Calc.	Graphic.	$t\gamma_{1s}$	Calc.
1.40 .....	1.075 .....	4.00	...	Not calculable	
1.90 .....	1.90 .....	3.40	.....	3.31	
2.35 .....	2.25 .....	4.20	.....	4.16	
2.35 .....	2.17 .....	4.20	.....	4.20	
1.60 .....	1.52 .....	2.80	.....	2.78	
1.30 .....	1.20 .....	2.30	.....	2.18	
1.25 .....	1.07 .....	2.00	.....	1.91	
1.60 .....	1.52 .....	2.80	.....	2.74	
1.60 .....	1.39 .....	2.70	.....	2.68	
1.60 .....	1.57 .....	3.00	.....	3.01	

Disregarding the first result, in which the quotient,  $\gamma_2 \gamma_1$ , is too small to make the method of calculation reliable, the coincidences are sufficiently near, especially if it be remembered that the values of the graphic method depend upon interpolation in an exponential curve drawn through two points, a rather uncertain process.

The point is that not only K but the value  $\gamma_{\infty}$ , the ultimate possible factor, must be considered.

In conclusion, it should be pointed out that the limitations involved in the special formula used, as to the quotient  $\gamma_2 \gamma_1$ , must be borne in mind, and also that the formula must not be applied to developers with a Watkins factor greater than 15. I hope Mr. Payne's difficulty is cleared to his satisfaction; if not, I shall be glad to discuss the matter further.—Yours, etc.,

S. E. SHEPPARD.

#### URANIUM-TONED IMAGES.

##### To the Editors.

Gentlemen,—I am much obliged to Mr. Wall for his offer of plates exposed in an H. and D. machine for further tests on the

of various uranium baths. I feel that the uranium processes are rather played out, and I suppose few now use them to recommend them, but, as the relative effects of different for intensification purposes seem still somewhat undecided, be worth while to make comparative tests that will give a result. Therefore, I shall be very pleased to accept Mr. kind offer, and will report results later.

sorry to hear of the fate of "Aylesford Bridge," as I well remember this picture. The clear yellow patches look like the much of "fading," but the metallic sheen could, I think, have been and I should have liked to have made an attempt at remedy. The pictures referred to by Mr. Wall are of the same mine, and a comparison would be interesting.—Yours faithfully,  
C. WELBORNE PIPER.

h Heath, July 1, 1906.

## TEUR" AND PROFESSIONAL—THE QUESTION OF ES FOR PHOTOGRAPHING IN SHOW PLACES.

To the Editors.

lemen,—Whilst operating in various parts of the country I find that the professional photographer is subjected to very treatment as compared with his amateur brother. At many of interest the amateur is allowed to take any photographs y wish to (and to sell them to a publishing firm for a ridiculous, if he be so minded) for a small fee, whereas the professional who is striving hard to earn an honest living, has to pay a fee. Surely he who is earning his daily bread should be d at least facilities equal to those granted to others who are pursuing a hobby.

ford Cathedral, Malvern Priory Church, Tintern Abbey, and Castle are instances in point where the fees to professionals are 10s. 6d. to £1 1s., compared with 6d. to 2s. 6d. to rs. This is manifestly unfair, and should be altered. No my fellow-readers in various parts of the country can corroborate my statements.

ing that you will find space to ventilate this matter.—Yours ally,  
WALTER COATES.

inetre Hill, Kingsdown, Bristol.  
June 30, 1906.

## FACTORIAL DEVELOPMENT.

To the Editors.

lemen,—In an editorial note on this method you speak of ource of error caused by the eye not getting accustomed for minutes to the dim red light of the dark room.

s a matter which certainly requires consideration in many

But the difficulty equally applies to the use of a dark room older plans of judging density by visual means in a dark and to speak of it as an "insurmountable difficulty" is surely strong, seeing that it is so easy to wait the few minutes ed for the eyes to get accustomed to the light, and to occupy ne by setting dishes, solutions, etc., ready to hand.

ay own case I happen to be red colour-blind, and a dark-room nation is to me probably nearer "darkness made visible" s the case with most persons. But this has not prevented me making the long series of experiments which led to the ion of the factorial method of development. I have always an orange and not a ruby illumination. It is twelve years the factorial method was given to the public, and it is being y thousands with success. If the difficulty mentioned is a ar to its use, it is certainly curious that it is now men- in print for the first time.—Yours truly,

ALFRED WATKINS.

eford, June 29, 1906.

a paragraph with which our correspondent is apparently in ment was intended to draw attention to an error which may to those who have to be continuously in and out of the dark The loss of a few minutes every time a plate is developed ly an "insurmountable difficulty" in the commercial sense.—B.J.P.]

## Dews and Notes.

MATT-ALBUMEN Papers.—Messrs. L. Trapp and Co., whose "matt-albumen" papers we were able to speak of in appreciative terms some time ago have done themselves and their customers a good turn by arranging at their premises, 8 and 9, Chiswell Street, E.C., a small exhibition, from which may be seen the great variety and excellent effects obtainable on these papers. The collection includes not only the results of simple toning and fixing, but of blue and other toning agents, the solutions for which are supplied by Messrs. Trapp. In choice of paper alone, however, the user is in the fortunate position of securing very varied results, according to his selection from the "15-kilo rives," cream and white crayon card (smooth and rough), hand-made paper and card (also cream and white) and linen grain paper and card. Those who can do so should certainly pay a visit to Messrs. Trapps' exhibition. It remains open until Saturday, July 21.

A CAUSE of Bad P.O.P.—A letter from Messrs. Barclay, 95, Farringdon Street, E.C., to the "Chemist and Druggist," says: "We recently sent some dozens of packets of sensitised postcards to a customer, and on some of them being opened they were found to be discoloured round the edges and unsaleable. We returned a sample to the makers to ask for their explanation, and they informed us the goods were quite fresh when they left their works, and the papers had evidently been exposed to the action of some strong chemical. In our stock there is no opportunity for sensitive material to come into contact with any chemical, and our customer said the same of his store, but suggested that as the cards had been packed with several pots of phosphor-paste, possibly the phosphorus might be the cause of the deterioration. We accordingly made an experiment by putting a piece of fresh P.O.P. in a box with a pot of phosphor-paste, and the following morning the paper was quite discoloured and unfit for use, although no smell of phosphorus could be detected."

KIRKCALDY Corporation Exhibition, 1906.—The Corporation of Kirkcaldy, acting in conjunction with the following local societies, namely, the Fine Art Association, the Photographic Society, and the Naturalists' Society, have arranged to hold an exhibition in the Corporation Halls, Kirkcaldy, during the coming autumn, opening on Wednesday, September 5, 1906. For the Photographic Section the receiving day is August 27. Mr. W. Crooke, of Edinburgh, will judge. There are three classes. Copies of prospectus and entry forms may be had from J. Rowan Thomson, C.A., 154, High Street, Kirkcaldy.

"CAMERA CRAFT," our San Francisco contemporary, has not been slow in recovering from the effects of the earthquake. Its May number reaches us, containing the story of how its entire April issue, copies, proofs, and MSS. were lost in the fire. Congratulations to Fayette J. Clarke on his speedy return to publication.

"THE World of the Camera."—Mr. Thomas Bedding, F.R.P.S., informs us that the number of applications from secretaries of photographic societies for his lantern lecture bearing this title has been such that early application for dates is advisable. Mr. Bedding should be addressed at 4, Duke Street, Adelphi, W.C.

TESTING of Optical Surfaces.—M. G. Meslin describes a very interesting method of testing optical surfaces (writes C. P. Butler in "Knowledge"), which is more widely applicable than the now well-known method of using Newton's rings and monochromatic light. By employing a grating instead of the parallel test-plate, a new series of interference phenomena are brought into play, and the most important factor from a practical standpoint is that these new bands are very distinct in ordinary white light, so that little special apparatus is needed. The grating is placed over the surface to be tested, either in contact or a few millimetres distant. An interesting distinction of these grating interference bands from Newton's rings is that they are scarcely coloured, being almost achromatic when viewed at an incidence about 45deg.; further, the diameters of the rings diminish when the incidence is increased, whereas Newton's rings increase in diameter under similar conditions. They may be rendered very brilliant by increasing the reflecting power of the surface to be tested, say, by silvering, and hence the method may be applied to the examination of metallic surfaces, and also of liquids, such as mercury.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
7.....	Hackney Photographic Society	Outing to Major Woolmer Williams House Boat, Taggs Island.
7.....	Chelsea and District Photo. Soc.	Outing to Leatherhead.
7.....	Blackburn Camera Club	Outing to Sunnyhurst Woods, Darwen.
7.....	South London Photo. Society	Outing to Shirley Hills.
7.....	Halifax Camera Club	Outing to Kelghley.
7.....	Worthing Camera Club	Outing to Patching and Clapham.
7.....	Aberdeen Photo Art Club	Outing to Stonehaven.
7.....	North Middlesex Photo. Soc.	Outing to Chase Village and Old Scunghate.
7.....	Redhill and District Cam. Club	Outing to Felsay (Holmbury).
9.....	Southampton Camera Club	Photographic Convention of the United Kingdom.
9.....	Bradford Photographic Soc.	"Print Retouching," A. Bracewell.
9.....	Royal Photographic Soc.	Ordinary Meeting. Nomination and Election of Candidates for Election.
10.....	Hackney Photographic Society	Enlarging by Daylight. H. F. Edmonds.
11.....	South Essex Camera Club	Lectures. Members.

THE HOVE CAMERA CLUB were fortunate in having splendid weather for their excursion to Amberley and Bury on 30th ult. Amberley with its castle, church, and old-world village took up the morning, and the afternoon was spent on the riverside between Berry ferry and Houghton, where some beautiful scenery was found. In the evening the party walked to Arundel, the only complaint being lack of more plates. The neighbourhood is an ideal one for the study of Sussex river scenery, and may be commended to all photographers.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Annual General Meeting held June 28, 1906, Mr. A. Haddon in the chair. The hon. sec. and treasurer read the annual report and balance sheet, which were adopted. The following were elected officers for the coming year:—Trustees, Messrs. A. Haddon and T. E. Freshwater; Hon. Lanternist, Mr. E. T. Wright; Hon. Librarian, Mr. E. J. Ferry; Hon. Recorder, Mr. Ernest Human; Hon. Sec. and Treas., Mr. H. C. Rapson; Committee, Messrs. R. Beckett, Hart, Smith, J. S. Teape, French, A. B. E. Fry, Furley Lewis, and W. R. Stretton. Delegates to the R.P.S., Messrs. H. C. Rapson and Ernest Human. It was arranged to hold the Annual Supper in the early part of October, in place of February as previously.

SOUTHAMPTON CAMERA CLUB.—Mr. A. E. Henley, who is the most successful worker in the Southampton Camera Club in floral photography, lectured on that phase of the art to his fellow-members on Monday, July 2. The lecturer claimed that no department of photographic work gave more increasing pleasure to those who specialised in it than does flower work, but he also pointed out that almost infinite patience was needed to ensure success. Among the points of an excellent lecture were the following: The flowers should never be cut immediately before use, since drooping at once begins; they should be cut at least 24 hours beforehand, and should at once be arranged in the desired fashion. They should then be laid in water in a shallow dish, the effect of which would be to set the blooms as much as possible in the narrowest place, and bring them to the time of exposure in fine condition ready for at least an hour's handling. The background should not be too near; 10in. behind a small subject, increasing as the subject was larger. The flowers should never be subject to the front light, but to a side light, and immediately in front should be a white foreground to throw as much light upwards as possible, while a mirror might be used at the side to concentrate light on to either foliage or blossoms, as proved necessary. The most successful studies would be found to result from yellow flowers and green leaves, pure white flowers needing careful treatment by reason of the strong contrasts. Exposure, which should always be made on isochromatic plates, should be full, while the yellow screen should be used the length of exposure with a four times' screen should range from 12 to 20 minutes. The lecturer gave practical demonstration of the method of fixing flowers and fruit on glass by means of pieces of cork fixed to the glass with Prout's cement—the only medium he had found successful, and produced a number of excellent prints illustrating the chief points in his lecture. The usual discussion, which was heartily entered into, followed, and the lecturer was cordially thanked for a most interesting lecture.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & COMPANY, 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, from two unmounted copies of each photograph must be sent with the application.

### PHOTOGRAPHS REGISTERED:—

R. W. Brown, Boulevard Studio, Weston-super-Mare. Photographs of the W. super-Mare Water Polo Teams.  
Isaac Perkoff, 186, Commercial Road, London, E. Photograph of Prof. A. Mische Elman.

A. H. M.—You can sue in the County Court from your town.  
E. B. B.—In our next.

CARBON.—Prove to the trade houses that you are able to bona-fide dealer's business.

BOOKS.—I would esteem it a favour if you would kindly recommend a book on (1) photographing interiors, (2) also one on retouching.—A. R.

(1) The Photo-Miniature, No. 30 (6d.); (2) "Retouching," Arthur Whiting, 1s. Both from Dawbarn and Ward, 6, Farndon Avenue, London, E.C.

RETOUCHING (Reply to C. P.).—Your specimens of retouching are above the average we receive—especially the female studies. Likeness is excellently retained, allowing for a fair and reasonable amount of flattery. Altogether, your methods are good, result in bright and pleasing finish. The male studies are not quite strong, an unnecessary amount of work having been placed on old man's forehead, and the very characteristic wrinkled likeness is left. Be a bit bolder in the grain with the men, differentiate more, and you will soon be capable of much better results.

S. ALSTON.—(1) We should prefer the Unofocal lens by the makers. (2) The cards obviously carried some of the alum the fixing bath with consequent decomposition of the hypo sulphur toning. There is no necessity to use alum at all if you want a hardening bath, formaline should be used.

D. R.—(1) We are not quite clear whether you merely wish to know the name of some commercial paper or formulae for making same. Chas. Zimmermann and Co. supply paper which answers to your requirements; and also a ready-made bath. (2) The paper will give the results you want, if the formulae on p. 10 of the Almanac for 1906 are followed.

CLOUD NEGATIVES.—It would be impossible to print such clouds without blocking out some of the upstanding details. Any orthochromatic plate with a yellow screen would give you such results.

LENS.—You had better select one of the anastigmatic lenses makers' lists in the "Almanac", working at f/6, which is quite rapid enough for portraiture. In a studio 20ft. long, cannot expect to get good perspective of panel portraits, a lens of the class we recommend to you, of about 10in. 10 length, will give you plenty of room for full-length cabinet figures, and, stopped down, will serve as an excellent wide angle lens on the 12 by 10 plate.

\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The Photographic Convention.—The earlier proceedings are reted this week. A reproduction of the group taken on Wednesday is presented. The Convention will meet next year at Hereford, under the presidency of Mr. Alfred Watkins. (P. 546.)

Some practical hints on "Copying Pictures" with orthochromatic plates and filters are given by Mr. Harold Baker. (P. 544.)

Some suggestions for the simplification and unification of "Optical nomenclature" are given. (P. 543.)

Simple, effective, and easily performed experiments are described by Dr. Scheffers, and from these a very clear grasp can be obtained of the principal lens aberrations. This might well form the subject of a society meeting. (P. 552.)

"Studio Blinds" and the best methods of hanging them are practically considered by Mr. Foster Brigham. (P. 550.)

Further experiments on the action of aluminium dark-slide shutters are described, also others with wood. (P. 542.)

Suggestions as to the rapid drying of gelatine films and plates are given. (P. 554.)

The correspondence as to the assistants' certificates again continues this week, and obviously there is still considerable interest in it. (P. 557.)

Mr. Comley brings up the subject of the "Proposed Society of Colour Photographers," and proposes to call a meeting in London shortly. (P. 558.)

Mr. Sands, of Oregon, calls attention to his work, noted in our issue of June 8, on "The True Cause of the Formation of the Latent Image," or "The Primordial Energy," as he prefers to call it. (P. 559.)

## EX CATHEDRA.

### Dark Rooms at Public Libraries.

According to an evening paper, the St. Pancras Borough Council is asked for a room at its public library to be used as a dark room for amateur photographers. This is the first time we have heard of such an application being made at any public library, and it will be interesting to see if it is granted in this case. There is very little question that a public dark room would be a great convenience to many amateur photographers who have only a very makeshift one at home, even if a small payment had to be made for its use. Now, a dark room in any public building would require some fitting up to adapt it for its purpose, and the question will arise as to whether the ratepayers' money can legitimately be expended in this way, even if there is a room available. Again, it would require consideration as to how the use of the room is to be granted to the many applicants there would no doubt be for it, and the time they would be allowed to occupy it. Then again, someone would have to be appointed to look after it, and keep it in useable order, for it is well known to those, dealers and others, who have dark rooms for the use of amateurs, the plight they are sometimes left in after an hour or so's occupation by some users. It will, as we have just said, be interesting to see if the application for a dark room at its library will be entertained by the St. Pancras Borough Council. If it is, it will perhaps serve as a precept to other public library authorities.

### A New Celluloid.

It would be a somewhat difficult matter at the present time to enumerate the different purposes to which celluloid is put, so many are they. Most of our readers are aware of the many uses to which it is put in connection with photography, such as xylonite developing dishes and the like—xylonite being only another name for celluloid. One of the most important uses for celluloid in photography, however, is films for supporting the sensitive gelatino-bromide film, either as rollable or cut films, and films for the cinematograph. The great inconvenience of the material for this latter purpose is its extreme inflammability, and the restrictions that are enforced where it is used in places of public entertainment. With regard to its inflammability when used as a support for negatives, that causes no practical inconvenience, though it is a little expensive as compared with glass, and therefore any substitute for it, with the same advantages, would be welcomed. According to the Vienna correspondent of the "Pall Mall Gazette," such a thing is now promised us. He says that a Bohemian chemist, at Gablonz, is reported to have discovered a perfect substitute for celluloid, much cheaper, and with-

out any of its dangerous properties. He adds that the new substance is very elastic, entirely non-inflammable, and an excellent material for working in. Further, he says that by a simple process articles made from it can be given a high and lasting polish; and it is said to keep its colour alike in sun and in water. If this new material fulfils all that is claimed for it, it would be safe to predict that a fortune awaits its inventor. But we have often read of non-inflammable substitutes for celluloid being invented before, but nothing has come from them. We shall wait with interest, and see what comes from this last one.

#### Dark Slide Shutters.

In our issue for March 30 we gave an abstract of a note by Dr. Neuhauss on the above, in which he stated that aluminium emitted radiations which would affect a plate and that wood and ebonite were permeable by violet and ultra-violet light. In our last issue, also, on p. 522 there appears a note on the same subject, and now it is reported in one of our German contemporaries that Herr Beckers, who is connected with one of the large camera factories at Dresden, has been experimenting, and the conclusions he comes to are somewhat reassuring, for aluminium, on account of its light weight, is specially suitable for this purpose. A shutter was removed from a slide and one-third of it was brought to a high polish in a lathe, another third was smoothed with emery paper, while the remaining portion was left matt and varnished. The shutter was then at once inserted in the slide, in which had been placed a very rapid plate, and the whole left for thirty-six hours and then developed. Not the slightest trace of any radiation could be detected. To test the permeability of ebonite and wood to the shorter wave lengths, rapid plates were exposed to a 25 ampère arc lamp at a distance of ten inches for ten minutes in the case of the ebonite, which was about one thirty-second of an inch thick, and in the case of mahogany and walnut shutters the exposure was an hour. The experiment was repeated with an hour's exposure to a brilliant mid-day sun, and in neither case was the slightest action detected. Whilst this is decidedly satisfactory, it need hardly be pointed out that there are not many worse places for storing plates than the dark slides, and the old advice of protecting the slides from direct sunlight as much as possible still holds good.

**Local Views.** The Cardiff Corporation have just announced the awards in their competition for the best ten prints illustrative of the district, and a committee were appointed to select others than the winning prints for illustrative purposes. What the precise lines were on which the awards were made we are not aware, but one can easily see that whilst however commendable such enterprise may be, there are many pitfalls in the road. Assuming that the idea was to obtain as pleasing views as possible of the place and district, it is obvious that one might have a purely pictorial rendering of a certain subject, which might be quite useless from the point of view of attracting visitors. On the other hand it cannot be denied that many local views are distinctly discouraging and possess but very little pictorial merit, if any. It is, in fact, an open question how far one may err in such subjects from the purely topographical standpoint, whether a purely artistic rendering or a mere plan is the better. It will be difficult, of course, to make a pictorial rendering of some subjects which are required for local guide-book purposes, but there is yet room for improvement in the majority of such things. Certainly

the idea of throwing open the subject to competition is more conducive to obtaining good work than when handed over to one person as a contract. On the other hand, we may question whether a prize of five guineas is enough to compensate anyone for ten views of a place, for even if the copyright was retained, the publication of the same in a local guide-book, which would probably be given away, must inevitably reduce the selling value of the prints considerably.

\* \* \*

**The Televue.** Just a year ago in our issues for 7 and 14, 1905, we described Professor Korn's apparatus or system of transmitting photographs by wire, now according to a New York paper, J. B. Fowler of Portland, Oregon, has invented another apparatus, which is said to give even more brilliant results than Korn's and it has been tested with very satisfactory results at 6,000 feet. The description is somewhat vague and unsatisfactory, but we give it for what it is worth. The cabinet embodying the receiving and transmitting apparatus of the televue is in many respects merely an elaboration of the ordinary telephone cabinet, but the switch and hook inside are declared to be wholly dissimilar. There is one extra induction coil and two extra batteries in each machine. The lens employed is similar to a camera lens, and images are transmitted in their natural colours. The disc for transmitting the image—that is, the glass before which is placed the person or object to be reflected at the opposite end of the line—is about 10 inches in diameter, but the receiving plate, where the transmitted image is discernible, is only about one and three-quarter inches in diameter. The two glasses are arranged that a person using the televue can have his eyes upon the lens where is reflected the image of a person at the other end of the line, and at the same time remain in the required position before the larger lens to enable the transmission of the image to the opposite terminal. The telephone transmitter is close by the listening lens where the picture is received, and the telephone receiver is held to the ear in the ordinary manner. The visual image in the seeing telephone is transmitted in the form of a photograph, and the apparatus is said to depend for its working "upon the variations in the electric resistance of a ribbon of selenium produced by variation in the intensity of a beam of light impinging upon it."

#### The National Portrait Gallery.

It would be interesting to know what proportion of professional photographers and portraitists per annum visit the National Portrait Gallery with a view to obtaining instruction from the pictures there on show, for they might learn much from them. Last week the forty-ninth annual report of the trustees of this gallery was issued as a white paper, and it seems from it that they are heavily handicapped for want of space. In the report it is stated that owing to the congested state of the galleries, the difficulty of finding space on the walls for the recent acquisitions continues to increase, and the attempt to maintain a chronological and historical arrangement of the portraits would soon become unavailing. The report goes on to say that the trustees had been in further correspondence with the War Office with regard to the future disposition of the site now occupied by St. George's Barracks, but up to the time of the report no reply had been received from the military authorities. Not only is more room required in the Portrait Gallery, but, also in the National Gallery, and there is no question that if the site of the Barracks could

had it would be a great acquisition to both institutions. We have before now expressed the idea that a national portrait gallery need not be confined to oil paintings, and that photographs might well be utilised when oil paintings are not available. In a national collection of portraits we take it that it is the portrait, the likeness of the individual, that is the main object. There are many persons who have distinguished themselves in politics, literature, the arts and sciences, etc., during the past few generations whose portraits should figure in a national collection, but no oil paintings of them are, perhaps, in existence, or if they are they are too highly prized by their families to be given to the nation. Still there are good photographic portraits of them existing that would be available. These could be enlarged and artistically finished in monochrome. The cost would not be great, even if it were paid out of the National Exchequer, and if the portraits were reproduced by either the carbon or the platinotype processes they would be as permanent as they were oil paintings. The National Photographic Record Association, through the influence of its President, Mr. Benjamin Stone, M.P., is fully recognised by the authorities of the British Museum, and they have allocated space for its photographs. Why should not the trustees of the National Portrait Gallery do the same for photographic portraits, if space were available? Until that is in prospect, of course, nothing really practical can be done. Still the subject should be kept in view.

\* \* \*

**Portrait of Turner.** While on the subject of national portraits, it may be mentioned that what has been pronounced to be an excellent portrait of the great painter Turner has just been brought to light. Part of the picture is said to be by the great artist's brush, and the remainder by that of another. Those who knew Turner well, Mr. W. P. Frith, R.A., the painter of the famous "Derby Day," amongst the number, pronounce the portrait as an excellent one. It appears that the picture was purchased for a trifling sum at a second-hand shop some years ago, but has only recently been cleaned, when its value was discovered. It seems that only three authentic portraits of Turner are in existence, and that one of them is little more than a caricature, interpreted by a fellow Academician on a "varnishing day." This recently discovered portrait is said to depict the great artist when in the height of his fame. Will the picture find its way to the National Portrait, or the Tate Gallery, where so many of his pictures are shown?

## OPTICAL NOMENCLATURE.

For a little confusion is caused by the free and easy nomenclature adopted by writers on optics, and perhaps this confusion is at its worst in that branch of optics that treats more especially of the action of the photographic lens. A very great deal might be said on this subject, for photographic optics is overloaded with terms that are inexpressive and often quite misleading, and is also deficient in terms that are required, but in this article we propose only to deal with such expressions as relate to distances of foci and separations, etc., of lenses. Much confusion exists here, for such terms as "focal distance" and "separation" are used in a variety of senses. When we come across the first term it is difficult to know whether it is used to describe the distance of a focus from the surface of a lens, or its distance from the lens node, or the lens pupil. Similarly, when we read of the "separation" of two lenses it may mean the distance between the second node of the front lens and the first node of the back, or

it may simply be descriptive of the distance between the two glasses. In our own work we have got over these difficulties by adopting the following very simple system.

The distance of a focus, or of either object or image, is measured differently according to circumstances. Sometimes we want the distance from the lens node, sometimes from the pupil, and very often from the principal focus, while occasionally it is desirable to describe the distance from the surface, or "pole" of the lens, as Prof. Sylvanus P. Thompson has very aptly termed it. In these cases it is easy to secure preciseness of expression by simply defining these various distances as "nodal," "pupilar," "extra-focal," or "polar" distances; the definite term focal distance is dropped completely, but if it had never been used in any other sense it would be very applicable to a distance as an alternative is inadmissible, as it has often to give a new meaning to an old term would, however, only add to confusion, and "extra-focal" is perhaps a better expression. It has been used in the same way for some time, and is therefore no innovation. Principal focal distance as an alternative is inadmissible, as it has often been used in a different sense; moreover it is very clumsy.

The same method may be applied to distinguish the various meanings of "separation" as applied to a doublet of two lenses. The "nodal separation" is the distance between the second node of the first two and the first node of the back one. The "pupilar separation" is the distance between the second pupil of the front lens and the first pupil of the back one. The "focal separation" is the distance between the second principal focus of the front lens and the first principal focus of the back lens. The "polar separation" is the distance between the inner poles of the two lenses, the "poles" being the points at which the principal axis of the system intersects the surfaces of the glasses. Of these terms "pupilar separation" is perhaps the least useful, while all the rest express distances that are frequently employed and are most useful, though in general they are all vaguely styled "separation."

This leads us to note the first example of deficiency in terms. There are many quantities, and even points, relating to lenses that at present have no definite names, and are commonly only referred to in a clumsy descriptive fashion. Occasionally we have to deal with the distances between the outer poles of a lens. This is, of course, the "thickness" in the case of a single lens that has only two poles, but in a doublet it has no definite name. We have found "polar length" to be amply descriptive, and very useful, and we suggest "nodal length" and "pupilar length" as equally suitable to express the distances between the first node or first pupil of the front lens, and the second node, or second pupil of the back lens. These terms are strictly in accord with the system of nomenclature we use and advocate, and no possible confusion can exist between the polar or nodal length and polar or nodal separation of a doublet. It is, however, obvious that the same method cannot be employed for describing the distance from the first principal focus of the front lens to the second principal focus of the back lens. We cannot describe this as the focal length, and so it is fortunate that the distance is one of no practical importance, though the "focal separation" is of very considerable importance, and appears in nearly all formulae relating to a combination of two lenses.

There are yet two more dimensions of importance, and these are the distances between the first and second nodes, and between the first and second pupils of a lens system. For these we suggest "nodal space and pupilar space." We have long used these two terms and find them very convenient. It will be noted that we have throughout this

article used the terms "first" and "second" to distinguish between the two nodes, or the two pupils of a system. This is not an innovation, as many others have employed the same expressions, which we think are distinctly preferable to the older and more clumsy, "node of admission" or "node of emission," and "entrance pupil" or "exit pupil."

As we have touched on errors of omission in nomenclature we must refer to an important one concerning a point, not a dimension. At present there is no recognised term for the central point of a pupil. "Pupil centre" is of course, servicable, but we should like to see the term "Abbe point" generally adopted. The corresponding

to travel in the direction of the arrow, and  $a$  is the focus image of an object point at  $A$ .  $A$  and  $a$  are therefore conjugate foci. In Fig. 1,  $F_1$  and  $F_2$  are the 1st and 2nd principal foci of the objective;  $N_1$  and  $N_2$  are the 1st and 2nd Nodes;  $P_1$  and  $P_2$  are the 1st and 2nd Pupils;  $P_1$  and  $P_2$  are the 1st and 2nd Poles;  $AF_1$  and  $aF_2$  are "Extra focal" distances;  $AN_1$  and  $aN_2$  are conjugate "Nodal distances";  $AP_1$  and  $aP_2$  are "Pupilar distances";  $AP_1$  and  $aP_2$  are "Polar distances";  $N_1N_2$  is the "Nodal space";  $P_1P_2$  is the "Pupil space";  $P_1P_2$  is the "Polar length," or "thickness" if lens is single;  $P_1P_2$  or  $P_2N_2$  is the "Pupil difference."

Fig. 1.

Fig. 2.

point in a principal plane is frequently styled "Gauss point" and this forms a good precedent for reminding people that the theory of pupils is due to Prof. Abbe.

Again if we go carefully into this theory of pupils we soon come across a dimension of considerable importance that has no name, and yet cannot be described verbally in much less than a sentence. That dimension is the distance from an Abbe point to the corresponding Gauss point or node. When the Abbe and Gauss points are separate, as they often are, the distance is one of considerable value. We suggest that "pupil difference" meets the case fairly well, though it is perhaps not quite satisfactory.

To make the proposed system of nomenclature quite clear, we give two diagrams. Fig. 1 illustrates a typical single view lens with separate nodes and pupils. Fig. 2 represents a doublet, and illustrates the terms relating to separation and length. In each diagram the light is supposed

In fig. 2, most letters have the same meaning as in fig. 1 but the pupils coincide with the nodes  $N_1$ ,  $N_2$ , and  $n_1$ ,  $n_2$  are the nodes of lens  $L_1$ , and  $P_1$ ,  $P_2$  are its poles;  $n_1/n_2$  are the nodes of lens  $L_2$ , and  $P_1/P_2$  are its poles;  $P_1/P_2$  are therefore the poles of the complete doublet;  $f_1$  is the first principal focus of lens  $L_2$ ;  $f_2$  is the second principal focus of lens  $L_1$ ;  $AF_1$  and  $aF_2$  are "extra focal distances";  $AN_1$  and  $aN_2$  are conjugate "nodal distances";  $AP_1$  and  $aP_2$  are polar distances;  $N_1N_2$  is the "nodal space," and also the "pupil space";  $n_1n_2$  is the "nodal space" of lens  $L_1$ ;  $n_1/n_2$  is the "nodal space" of lens  $L_2$ ;  $n_2/n_1$  is the "nodal separation" of lenses  $L_1$  and  $L_2$ ;  $P_2/P_1$  is the "polar separation";  $f_1f_2$  is the "focal separation," commonly denoted by the formula  $f_1 - f_2 - d$  when  $f_1$  and  $f_2$  are the focal lengths of the two lenses and  $d$  is their nodal separation;  $P_1P_2$  is the "polar length" of the doublet;  $n_1n_2$  is the "nodal length."

## COPYING PICTURES.

THE copying of pictures in colour is difficult work, and is seldom done properly by the average photographer, who is often content to use an ordinary plate, or possibly an orthochromatic one; and he relies on the colour-sensitiveness of the plate to render correctly the colours of the picture. An orthochromatic plate without a "yellow screen" or "light filter" is scarcely any better than an ordinary plate. When choosing a plate for such work, one should be selected that is sensitive, to some extent, to the red rays of the spectrum. The ordinary orthochromatic plate is very good as far as regards the yellow, and produces very good results in copying water-colour sketches where there is not great range of colour, but where there are strong contrasts, and especially much red (such as a portrait of a man in scarlet robes), a plate that is more sensitive to

red should be used. Some operators use the ordinary orthochromatic plates, sensitive to yellow, and bathe them in a red sensitiser themselves; but the average photographer, who only occasionally has such work to do, would find it much too troublesome and uncertain, as he would have no proper drying cupboard, and the danger of fogging and uneven drying of the film would be very great. It would be better to use one of the commercial red-sensitive plates. It is, of course, advisable to keep to one kind of plate for each light filter used, as the amount of correction of screen and plate can then be fairly gauged, and also the increase of exposure necessitated by each screen, as the increase depends on the degree of colour-sensitiveness of the plate. It will readily be understood that if a deep orange screen is used a greater increase of

sure will be necessary with a plate sensitive to blue and only than would be the case with a red-sensitive plate, or similar conditions.

The depth of the light-filter selected depends on the amount of correction required, as it is quite possible to over-correct, and render reds and yellows too pale and blues too dark. Good lenses are expensive things to buy, but if much work is contemplated it is cheaper to spend ten or fifteen shillings on a really good one than to put up with home-made make-shifts, although it is quite possible to make very serviceable lenses when the photographer knows what he wants. The fiercer forms of screen, thin pieces of optically worked glass of a pale brownish yellow with a suggestion of green, are optically useless for copying pictures; they may answer very well for rendering autumn tints more truly, but are of little value when brilliant colours have to be rendered into monochrome. The most useful for general purposes is of a pale orange, and when laid down on a piece of white paper should show an inclination to red.

#### Purchased and Home-made Filters.

The position of the screen is of no importance—either before or behind the lens, as may be most convenient, but the easiest method of holding it in place is to form a rebate, behind the panel covering the lens, with strips of hard cardboard, or better still, thin "millboard" used by bookbinders. This method of holding the screen necessitates a larger screen than if it were used in front of the lens, but when they are made by the photographer himself the larger size costs practically no more than the smaller one. Several screens should be made of varying depths for different subjects. A method of making the screen at home may be adopted. The pieces of tinted plate glass can be coated with clear gelatine, which is allowed to set on a level surface, to insure an even thickness of film. It must be protected from dust until dry, and then dipped in a solution of aniline dyes until the required colour is obtained. Penny packets of dyes will answer quite well, and an orange dye to which a small quantity of red has been added should be used, and the coated plate dipped in it until it has absorbed the necessary amount of colour; it should then be rinsed and put away to dry, taking due precautions against dust. If a deep screen is desired, two coated pieces of glass can be used and bound up face to face. No other method can be tried, and is perhaps easier than the one just described. A piece of non-curling celluloid film is used, without exposure to light, washed free from hypo, and stained; when it is dry it can be bound up between the pieces of patent plate. A clearer and brighter screen can be made by cementing the finished stained film between the glasses with Canada balsam, in a similar manner to that used for mounting microscopic slides. The glasses are warmed and covered with the balsam, and laid together with the stained film between, half a dozen strong spring clips are placed round the edges, and the superfluous balsam and air-bells squeezed out. The screens should remain under pressure for as long as convenient, several days if possible, in a warm place. The hardened balsam at the edges is scraped off, and the screen cleaned for use.

#### Exposures Under Glass and Out-of-doors

Having secured the screens by making or purchase, they must be tested, to ascertain the amount of correction they give and the exposure they need. An important point must always be remembered, and that is that a screen which increases the exposure ten times when working indoors will need twenty times out of doors, as the glass of windows itself acts as a yellow screen and cuts out some of the blue rays. When the tests are being made an exposure meter which tests the actinic value of the light is necessary. The tests should be made with the kind of plate to be used in the actual work of copying,

and a lithographic print in colour, or a colour chart, can be used as the testing object.

#### Avoiding Reflections and Glitter.

When the actual work is begun, several precautions will be necessary, especially when working away from home. First, a good exposure meter is most valuable, as the subject to be copied may be in a difficult place, and the light may be most misleading as to its actinic power. A large piece of thin black cloth, large enough to cover up the camera, lens, and legs, is most useful, as they may be reflected in the varnish of the picture. If the cloth is large enough to suspend in front of the picture and cut off all other objects, it is possible to secure a good copy through the glass, as in some cases the removal of the glass is impossible. A hole must be provided in the cloth for the lens to peep through. It is possible by this means to photograph a whole group of pictures under glass, but a very large black screen is necessary, especially when a long focus lens is used.

It is often difficult to avoid "glitter" on the surface of the picture, especially if it is an old one and highly varnished. The lighting needs great care to avoid this trouble; a large high side-light is better than top-light, and a slight tilt of the picture downwards will generally get rid of the "glitter" trouble. The camera must be tilted up at exactly the same angle as the picture is leaning forward. Copying out of doors is very troublesome, on account of reflections, and the probability of the object being shaken by wind and damaged by rain.

#### Exposure Maxims.

Exposure is a most important point. Under-exposure is hopeless, it can never be cured; but over-exposure can often be put right. In copying old pictures prolonged exposure and restrained development give the best results. It is quite useless to attempt to photograph an old picture without a deep screen, as otherwise little besides the cracks in the paint will be seen in the print. Some authorities advise focussing with the screen in position. With a dark picture this is well-nigh impossible, and with a proper screen is quite unnecessary, for it should make no difference at all to the focus, even when the lens is used at full aperture.

Better results are obtained by exposing a long time in a dull light than by short exposure in a bright one. In the days when light-filters were not invented good copies of pictures were obtained by this means; and although some operators, at the present time, prefer to do all such work out of doors, we are convinced that the results are not as good as those done under glass in a slow light; the only advantage obtained out of doors is the reduction in exposure. But the gain in this direction is not so great as would appear at first sight, as the light-filter needs twice as long out of doors. And in a dull light indoors a paler screen may be used with equal correction as compared with a deep screen outside.

The development of such exposure needs great care, as the plates used should be decidedly sensitive to red rays, and a very small amount of light must be used, and that of a deep red. The plate should be exposed as little as possible to the dark-room light, and should be kept covered during development as much as possible.

As full exposures are advised, restrained development is necessary, and the factorial method of timing is advisable. But if the exposure has for some reason to be cut shorter than the full one recommended, a rapid developer, such as metol, may be used. It is not always possible to give the exposures that will need restrained development, as they will often extend to hours and not minutes. In the case of dark stained-glass windows, it may become almost days, when working large sizes.

HAROLD BAKER.

# THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

## TWENTY-FIRST MEETING IN SOUTHAMPTON.

THE finest of summer weather marked the opening of the Convention, on Monday last, at Southampton. The headquarters, at the Philharmonic Hall, Above Bar, was the scene, on Monday morning, of the arrival of many figures well known at previous meetings; and, in the afternoon, when the formal proceedings commenced, the hall was crowded by a large company, among whom were Mr. E. J. Humphery (President), Mr. C. H. Bothamley (Taunton), Mr. W. Taylor (Leicester), Mr. and Mrs. F. A. Bridge, Mr. S. G. Kimber, Mr. F. W. Hindley (London), Mr. A. L. Henderson, Mr. and Mrs. R. R. Beard (London), Mr. and Mrs. Snowden Ward (London), Miss Goodwillie (Derby), Mr. A. Horsley Hinton (London), Mr. George E. Brown (London), Mr. A. Seaman (Sheffield), Mr. W. E. Dunmore (London), Mr. W. H. Smith (London), Rev. T. Perkins (Blandford), Mr. P. R. Salmon (London), Mr. Godfrey Bingley (Leeds), Mr. T. Scotton (Derby), Mr. T. Manly (London), Mr. P. Lenthardt-Thornton

(London), Mr. B. Tompkins (Leeds), Mr. H. J. Comley (Frome), Mr. P. Muirhead (Glasgow), Mr. T. K. Grant (London), E. Cliffe (London), Sydney A. Pitcher (Gloucester), Mr. E. Stebbing (Paris), C. L. Burdick (London), Mr. Walter and Mrs. Potter (London), C. Phipps Lucas (London), C. E. Kenneth Mees (Croydon), J. W. Eadie (London), Wilfrid Emery (London), J. H. Baldock (Croydon), C. S. Baynton (Birmingham).

The Conference was welcomed by the Mayor of Southampton (Mr. Henry Cawte), who, in a few appropriate words, expressed his pleasure at the selection of Southampton as the meeting place of the Convention. The President then delivered his address. The meeting then passed to the reading of the papers set down for the afternoon. The first, by Mr. Harry Thrift, B.A., was summarised by Mr. Bothamley; that by Dr. Stevenson was read by Mr. Snowden Ward; and that by Mr. Bothamley was read by the author.

## THE PRESIDENTIAL ADDRESS.

LADIES AND GENTLEMEN,—As you are probably aware this is the twenty-first year of our Convention, our coming of age, so that putting aside the frivolities of our youth, it is our duty to take a more serious view of our future, and while profiting by the lessons and failures of our childhood, determine to use to the utmost of our powers the infinite possibilities of our marvellous helpmate, photography.

The field is so vast, that, like children gazing for the first time on the mighty ocean, we feel our insignificance and realise how feeble are our greatest efforts in comparison with the marvellous powers of nature; yet, by utilising to the utmost of our strength those powers which nature provides, we may do much to guide them to our own use, and render infinite service to our fellow-men.

In the pursuit of photography, whether as an art or a science, there are three gifts which we should especially cultivate, if we are to achieve success.

Imagination—Observation—Industry—without these we can do nothing worthy of our art.

We must cultivate our imagination not only to give us a poetic inspiration for our art, but to suggest the infinite possibilities of the scientific application of photography.

And now let us go back to our childhood and read that fascinating story, which fired our imagination in our earliest days, "Beauty and the Beast."

You will remember that when the Beast had to leave his beloved Beauty behind, he gave her a glass, in which she could see him at any time, however great the distance that separated them. Does not this simple story of a genius of poetic imagination lead us to determine by the study of our art to produce by photographic means the same power of producing on the sensitive plate the pictures which Beauty saw in her mirror.

Let us look forward to the time when photography shall reveal to us the Martians holding their Conventions, and bring Venus to our very doors.

With the marvels of the Röntgen rays before us it is not difficult to conceive the time, when photography shall reveal to us all the hidden treasures of the earth; and the camera shall replace the pick and shovel of the prospector; when the depths of the ocean shall give up their secrets, and even the spiritual world may become visible.

Give your imagination full play and you will realise how infinite are the possibilities which lie within our reach.

And now to consider observation. As imagination will lead you to form your ideals, so observation will teach you the means by which those ideals may be attained.

With your camera as a companion, a new joy will be added to your country rambles; and you will be led to observe the beauties of all animate and inanimate nature; and in the quiet of your study reap

the harvest of knowledge which your camera has provided for you. To the botanist, the entomologist, the lover of birds, or student of Nature generally, photography will open up new worlds, and fire the imagination with the infinite beauties which reward our work. But on this subject I must not dilate now, as in a paper which you will hear on Thursday, Mr. Martin Duncan will lead you through those pleasant paths, and will, I trust, find many ardent followers in that fascinating study.

Whether you are astronomers, geologists, architects, or whatever your special hobby may be, the camera by training your power of observation will do more to help you than all the Education Acts, whether of Conservative or Liberal politician.

Having given free rein to our imagination, and cultivated the faculty of observation, industry will follow of necessity. But it will be the industry which is a labour of love, not the forced task of the hireling. You will become a slave to your work, but your work will be the greatest joy of life, your success will but stimulate you to fresh efforts, and you will never know the misery of an idle and purposeless life. And the joys of the camera may even enable a millionaire to endure existence.

Photography has no limits, and aided by the gifts of imagination, observation and industry can conquer all worlds, and reveal all the hidden mysteries of Nature.

My appeal is not made only to you, gentlemen, but even more to the ladies who add such charm to our meetings.

For to women photography opens up a vast field for scientific research, for which they are even better qualified than men. For though women are but ill-equipped to compete with men in labours which tax the physical powers, in scientific research they possess all the necessary qualifications. Their imagination is greater, their powers of observation more accurate, and their industry as great, if not greater. Science in the past has had few women workers; one brilliant example we have in Madame Curie, the joint discoverer of radium.

Let us hope that photography will lead many of our lady members to emulate her great deeds, and shed a bright lustre on our Convention.

Let us hope that by the next or some subsequent Convention we may have made such progress, that not only the bones and structure of the body shall be revealed to sight, but that every pulsation, every tremor and vibration of the nerves shall be recorded on the sensitive plate or screen, so that every degree of pain or pleasure shall be subject to exact measurement, and the health or sickness of a patient shall no longer be subject to the guess work diagnosis of the physician, but shall be recorded so clearly as to be a matter of mathematical certainty. The mysteries of microbic fermentation shall cease to be mysteries, and our food and drink shall be freed from all impurities, our lives prolonged, and our happiness increased.

will not permit me to dwell on the æsthetic or commercial of photography, its value to the shipbuilder, the investor in rises in distant lands to record the progress of the works, and thousands of kindred applications. Enough if I have led you in small way to realise the vast field of photographic usefulness before you.

may think me a dreamer and a visionary: but remember that

the dreams of yesterday are the realities of to-day; and the visions of to-day the commonplaces of to-morrow.

Imagination will enable you to soar into the realms of the infinite.

Observation will reveal all the hidden beauties of the hitherto unseen.

Industry will level the mountains which impede the path of progress, and open up vistas of undying joy.

## IONISATION OF PHOTOGRAPHIC PLATES ON EXPOSURE TO LIGHT.

By HARRY THRIFT (Fitzgerald Research Scholar, Trinity College, Dublin).

effect of light on a photographic plate is to ionise it, it is a able assumption that there ought to be a difference in the cal resistance of the plate before and after exposure to light. this idea in my mind, I endeavoured to measure the resistance narrow strip of film. I found, however, that the resistance of in the form sold was so high that I could not obtain suffi- accurate measurements of it. Consequently, I obtained of the emulsion from which the plates are prepared, and I that when this was carefully melted its resistance was quite n measurable limits. In the first place, I stretched two um wires on a glass plate, and poured a small pool of the ion over the wires. I then connected up these wires in the ary way in a post office box, and measured the resistance of the ion between them.

ound, firstly, that owing presumably to there being traces of salts as ammonium bromide left in the emulsion it behaved as electrolyte, and that the polarisation was very much too great limit of its resistance being measured in the ordinary way by is of a galvanometer. I overcame this difficulty by using two ar resistances of emulsion in two of the arms of the bridge, and using an alternating current and a telephone. By this means is enabled to measure the resistance of the emulsion, but I could t no change on exposure to light. Suspecting, however, that effect of light would be almost entirely a surface action, I ted a new plan.

### The Apparatus.

sealed two pairs of platinum wires by means of glass at stance of about 2mm. apart and about 3cm. long. Then, on ing these into the emulsion and on carefully withdrawing, I ined two exceedingly thin and fairly stable films.

n obtaining a balance in the bridge, keeping one film in the dark exposing the other to light from an incandescent electric lamp, I led to believe that the resistance of the exposed film diminished. ver, on trying illumination of other kinds this result appeared o means certain, and it occurred to me that perhaps the change ue to change in temperature rather than to the action of light. s was confirmed by finding that a ruby incandescent lamp rod- ed a greater diminution of resistance than an ordinary incan- cent lamp. This change in resistance, owing to temperature nges, is in itself interesting. I found that the ruby lamp, at distance of about three feet, produced a 10 per cent. change he resistance of the film, although the change in tempera- e produced was exceedingly small. In order to get

over this difficulty I tried exposing the film to diffused daylight, taking care to keep the temperature constant. I found that the resistance of the exposed films increased instead of diminishing, and that consequently light and heat had precisely opposite effects on the resistance.

### The Resistance of Gelatine.

The next point was to investigate the effect on pure gelatine, as it is known that light has an effect on a solution of gelatine after remelting. I therefore dissolved some pure gelatine in water in a dark room, and made similar films of the solution. I found that, on exposing one of the films to diffused daylight, in this case, also, the exposed film increased in resistance. This also, as far as I am aware, is not known; but the change in the resistance of the gelatine left the question as to the change in the resistance of the silver bromide in the film on exposure to light still unsettled. I made some experiments in order to try and obtain a film of silver bromide by first forming a film of ammonium bromide, and then dipping this into solution of silver nitrate, but I found that I could not form a film of the silver bromide in this way owing to the nature of the precipitate obtained.

The next step was to try and obtain films by having the silver bromide in collodion. I dissolved some ammonium bromide, ammonium iodide, and cadmium iodide in collodion in the proportions recommended for making plates, and formed a film of this solution. I immersed this film in an alcoholic solution of silver nitrate. The excess of silver nitrate on the film left the resistance too small for any change due to light to be observable, and also the drying of the collodion film introduced uncertainty. Consequently, after the formation of the precipitate, I washed away the excess of silver nitrate, and left the film immersed in distilled water during observations. Although I have not as yet completed my experiments, there seems little doubt that the resistance of this also increases on exposure to light. I intend to obtain a deposit of pure silver on a glass plate by means of Rochelle salts and silver nitrate, and to convert this into silver bromide by exposing to bromine vapour, and then to experiment on the film of silver bromide thus produced.

The increase in resistance on exposure to light, if established, seems very remarkable, and would appear to be evidence against the theory that the effect of light is to deposit free silver. Possibly the explanation may be that aggregation takes place instead of the ionisation that I had originally thought possible, or that perhaps bromine is set free in the film, analogous to the well-known fact that chlorine is given off on exposing silver chloride to light.

## DIFFERENTIATION OF B. TYPHOSUS AND B. COLI COMMUNIS BY MEANS OF THE PHOTOGRAPHIC PLATE.

a following facts which recently formed the subject of a com- munication to the "British Medical Journal," are, I think, of icient interest from the photographic point of view, to merit the sideration of the Photographic Convention.

The gelatino-bromide photographic plate is sensitive to direct lication of the products of certain bacterial cultures in a very arkable manner, and the effect on the plate is variable with the eial nature of the bacteria to a degree which renders easily pos- le, in at least one important case, a discrimination between acteria otherwise difficult to differentiate.

My observations have been mainly confined, so far, to the typhoid illus and the B. coli communis.

Cultures of these bacilli are made in broth, samples of the same th being used for each culture. After, say, twenty-four hours a y drops of each culture are placed upon the sensitive surface of a otographic plate and spread so as to wet an area of any desired

extent—say, 1 cm. or 2 cm. in diameter. (In general, 0.2 c.cm. of the culture has been allowed to spread by itself upon the plate, covering an area of about 1 square cm.) This is done in a red light sufficiently faint to avoid sensible fog upon the plate. An opaque cover—an empty developing dish will do—is now turned over the plate, and it is left thus screened for about forty minutes.

The cover is now lifted and the superfluous fluid upon the wet areas drawn off with a pipette. No change is observed at this stage of the experiment. The plate is then developed in the usual manner, and during development it is best screened from light. It will now be found that the moistened areas develop with very different densities of silver deposit. The coli culture produces a full and marked reduction of the salt. There has progressed over the area wetted by this culture an action similar to the formation of a photogenic material in the film. But where the typhoid culture has acted the result is quite different. Only a very faint deposit is, in general.

obtained. And if the plate has, in fact, been exposed sufficiently to the red light (either wilfully or incidentally) to produce a general fogging, it will be found that its effect is even inhibitive and its presence marked by an area almost free from reduced silver.

The following points are of interest, but can here only be briefly noted:—

(a) The discriminative action is the same, with some variation in degrees of distinctness, when typhoid and coli cultures of the same age are compared at very different periods after inoculation. Thus, cultures of these two organisms in broth compared, after four hours' growth and after thirty-three days, react as above.

(b) The activity of each increases with time up to a certain age which has not been accurately ascertained. This activity possibly varies with the physical conditions attending culture, but may be taken as increasing from shortly after inoculation to four days of growth.

(c) A coli culture of 24-hours age, when compared with a typhoid culture of any age (tested up to thirty-three days) gives the more marked reducing effect.

(d) After a few hours' growth the broths may be boiled and thus sterilised, and the differential effect upon the sensitive surface persists.

(e) This discriminative reaction has been obtained with four cultures of coli from different sources, and with five typhoid cultures from different sources.

(f) It will be found that if the sensitive plate is wetted with tap water and also with sterile broth, and simultaneously applications of

the cultures are made—four separate areas being thus prepared for comparison—the typhoid and sterile broth do not differ markedly in their actions upon the silver bromide, whereas the effect of the water has been intermediate between that of the coli and the typhoid. It is known that water is to some extent a sensitiser.

(g) The time of exposure of the plate to the application of the cultures has varied between 10 and 90 minutes, and the discriminative action of 24-hour cultures found to be best marked with an exposure of 45 minutes. But from at least 10 minutes exposure upwards difference is obtained with any broths in which there is a visible growth.

(h) While in some of the earliest of these observations, and before I had gained experience as to the best methods to employ, a few cases occurred in which the distinctive difference was not so markedly marked, in all my recent observations, twenty-four in number, I have unfailingly obtained the differential effect.

(i) Finally I have observed that if pools of well-grown coli or typhoid broth cultures are poured on a photographic plate exposed to light, a reduction of silver is seen in a few minutes with development. After about thirty minutes the deposit due to the typhoid broth is distinctly darker than that due to the coli broth. If the pools be now poured off the sensitive plate the difference reaches its maximum, but as the gelatine dries the distinction almost completely lost. Tap water has no visible effect, except the swelling of the wetted gelatine of the plate.

WALTER C. STEVENSON, M.D., D.P.H.

## USEFUL NEGATIVES

THE applications of photography as a recording agent have special prominence at this meeting of the Photographic Convention, and it may therefore be useful to call attention to some points in connection with processes which are of value in improving the printing quality of negatives which for some reason or other have not turned out well in the first instance. It is a counsel of perfection to say that in such cases the proper procedure is to make another exposure with a view to making a good negative; everyone with experience of record work knows that this is often impossible, and in the case of pictorial work the particular combination, grouping, and light and shade may never be repeated. We must therefore have at our command trustworthy methods by which unsatisfactory negatives can be made at least capable of giving passable prints. I purpose confining attention to chemical or photo-chemical methods such as may rightly be applied to negatives taken for record purposes.

In the first place, when a negative is of sufficient value to make it worth while to improve it, a diapositive should be made first of all, so that the negative can be reproduced in case of accidents. The writer's procedure is to apply the improving treatment to the diapositive and to reproduced negatives made with its aid, the original negative being left in its original condition.

It is scarcely necessary to point out that in making the diapositive or reproduced negatives there is abundant opportunity for effecting improvement by paying attention to the conditions of exposure and the manner of development, and very often the two processes will yield the desired result, especially if full advantage is taken of the widely different characteristics of the available brands of plates. The range of possibilities is widened in an important degree if the diapositive and the reproduced negative are made in a camera instead of in a printing frame, and I recommend this procedure more particularly in the case of negatives whose main defect is lack of contrast.

Referring briefly to one or two points to which sufficient attention is not always given, I would point out that in making a diapositive in a printing frame from a very thin negative it is worth while to adopt the old practice of exposing with the printing frame at the bottom of a box about 2ft. deep, with blackened sides and internal dimensions not much greater either way than those of the printing frame. This practically means printing with a parallel beam of light, and there is a noteworthy reduction in the amount of scattering. Again, when printing on a plate from a diapositive or negative which has very strong contrasts it is worth while to use a backed plate, whether in the camera or in the printing frame.

Passing now to the application of chemical methods of intensifying

## FROM POOR ONES.

and reduction, I think it may be safely said that many failures are due to the fact that the film operated on was not in a suitable condition, either as a whole or, perhaps, only in parts. When a gelatine film has been dried, it requires prolonged immersion in water to properly soften it again. Personally I should not think of attempting either intensification or reduction unless the plate has been immersed for at least an hour, and I prefer to leave it in water overnight. In the case of gelatine with a repellent surface it is advantageous to add a little ammonia or a little acetic acid to the water.

Plates or films that have been handled are very likely to have unclean surfaces, and after they have been soaked in water it is a good plan to rub the surface of the film with a clean plug of cotton wool dipped in a mixture of about equal parts of absolute (not methylated) alcohol\* and water, to which a little ammonia may be added if much greasiness is suspected. The alcohol should be thoroughly washed away, care being taken that the film is not touched by the fingers.

### Intensification.

Of all the various processes of intensification, I find none quite so satisfactory as the method of bleaching with mercuric chloride, and afterwards treating with the ferrous oxalate developer as recommended by Mr. Chapman Jones. It gives excellent results, the image has a fairly well ascertained composition (which is unusual) and if one treatment has not sufficient effect, the process can be repeated more than once. On the other hand, careful attention must be paid to certain points. The negative and positive must have been thoroughly washed after fixation, the surface of the film must be quite clean, and must not be touched with the fingers during the processes, the mercuric chloride solution must contain a small quantity of hydrochloric acid, and the mercuric chloride must be thoroughly washed out. Lastly, but by no means least, the development with ferrous oxalate must be carried out exactly as Mr. Jones recommends, for, if it is not, there is often difficulty in getting the image developed right through, especially after treating with mercuric chloride, more than once. The points with regard to the developer are: (1) It must be fresh; (2) it must contain a somewhat high proportion of potassium oxalate. Mr. Jones's formula is: Saturated potassium oxalate solution, six parts; saturated ferrous sulphate solution, one part. Negatives intensi-

\* The spirits of wine, which can be obtained from any of Messrs. Gilbey's agents in wine quart bottles at about 4/-, is pure and sufficiently nearly absolute alcohol for ordinary photographic purposes.

by this method, with both single and double treatment, are obtained.

record method of intensification which cannot be repeated, but which can be applied in succession to a diapositive and a negative produced from it, is the well-known uranium intensifier. It gives the printing opacity by reason of the colour of the deposit, or to more correct, of the compound which forms the image after intensification. Usually the process is carried out by mixing solutions of uranium nitrate and potassium ferricyanide (3 or 2 in 1 in each case) and slightly acidifying with acetic acid. It is an initial condition of success that all hypo (sodium thiosulphate) have been washed out of the film, but even with due precaution in this respect there is usually a distinct staining of the film where there has been no deposit of silver. This tendency to staining is lessened by the presence of the acetic acid, but is not altogether prevented.

A modification of the process devised some years ago by J. Le N. is, in my experience, a great improvement, and deserves more mention than it has hitherto received. In this modification the ferricyanide and the uranium compound are applied successively not simultaneously. The properly washed negative is immersed in a 5 per cent. solution of potassium ferricyanide, and allowed to remain therein until the silver image is completely acted on. It is then washed, to remove the excess of ferricyanide, but the washing should not be longer than is necessary for this purpose. The image is then immersed in a dilute solution of the uranium compound. It should be specially noted that it is useless to immerse either uranium nitrate solution or uranium acetate solution. It must be uranium chloride. The latter compound is easily obtained, and if it not at hand the same result can be secured by using a solution of uranium nitrate to which common salt has been added, in amount equal to about half the weight of the uranium compound. By this modification all risk of staining is practically eliminated. The intensified image should be washed for a short time, but prolonged washing must be avoided, especially if the water is hard. It should be borne in mind that the printing opacity of uranium-intensified images is mainly due to their colour, and to secure the maximum possible effect, all printing from such images should be done in light relatively rich in blue rays, such as daylight or the light from the electric arc, or from burning magnesium. To print such images by ordinary gaslight or lamplight is to throw away a large proportion of the benefits that might be gained.

Let us now consider certain processes of reduction which can be applied for removing (1) general fog, (2) reducing the general opacity of a negative, (3) affecting the printing contrasts. The potassium ferricyanide reducer is well known, and it remains on the whole the best for the removal of general fog, and for reducing the general opacity of the negative without lowering the contrasts. Used in a somewhat concentrated form, it to some extent increases the printing contrasts by its relatively more rapid action on the thinner parts of the silver deposit.

Sometimes it is found that this reducer acts irregularly, but the use of such action is obvious and is easily removed. The hypo solution which constitutes the bulk of the reducer is much denser in water, and does not mix uniformly with it. If, therefore, the plate or film is taken out of water and immersed at once in the reducer, rapid and somewhat violent agitation is necessary to cause the reducer and the water in the surface of the film to mix perfectly, and it may quite easily happen, if the solution is concentrated, that it acts on the image before there has been admixture, with the result that the reduction of the image takes place in streaks instead of uniformly. The remedy is simple. The plate, after being thoroughly wetted, should be immersed in a plain hypo solution of the same density as the hypo that is to be used in the reducer. It is then drained for a few seconds, and then immersed in the reducer, almost perfect admixture is obtained at once, and any unevenness in action is prevented.

## CONVERSAZIONE

The official reception was held by the President and Mrs. Humery, in the Philharmonic Hall, on Monday evening, when a large number of ladies and gentlemen were present. The hall provided every facility for the social side of the Convention and for the inspection of the trade and other exhibits. The largest and, perhaps, the

The solution of sulphate of cerium peroxide introduced by Messrs. Lumiere I find to be a very useful reducer. It acts with moderate rapidity, and is not, in my experience, liable to produce stains, though it is better not to handle the plate with the fingers whilst it is in the solution. This reducer tends to reduce the printing contrasts, though not to the same extent as ammonium persulphate.

If this effect is borne in mind, it may be used with success for the removal of general fog, though for this purpose I consider it far less suitable than the ferricyanide reducer. Ammonium persulphate, also introduced by Messrs. Lumiere, is of special value in reducing contrasts, and at present has no rival from this point of view.

It is stated to be very liable to produce stains, and it is commonly asserted that the stains are due to hypo (sodium thiosulphate) left in the film owing to imperfect washing. This latter statement is an example of the guessing which is still far too common in connection with photographic processes. If it had been considered that the persulphate is a powerful oxidising agent and rapidly and completely oxidises any hypo (sodium thiosulphate) with which it comes in contact, it would have been seen how improbable the explanation referred to is. I find, as a matter of fact, that negatives may be taken from the fixing bath, washed for not more than a minute, and immersed in the ammonium persulphate solution without any stains being produced. I do not recommend this as a usual practice, but it seems to dispose of the view that hypo is the common cause of staining with this reducer. Of course, if the hypo, instead of being uniformly diffused through the film in comparatively small quantity, is present in a concentrated form at any particular point, as it would be if hypo solution were dropped on the film, or if the film were touched with fingers to which hypo was adhering, then the conditions would be different, and a local stain might result. Personally I have been somewhat fortunate in avoiding staining when using the persulphate, and when stains have occurred I have almost invariably been able to trace them to handling the plate whilst in the reducer with fingers that were not so clean as they ought to have been. Consequently I always use some form of lifter, and avoid touching the film, even at the edges, whilst it is charged with persulphate solution. Another statement which has been made concerning the persulphate is that it only reduces when the solution is acid. My observations are at variance with this statement. It is quite true that in order to secure fairly rapid action, the solution must be distinctly acid to litmus paper. I find, however, that reduction will take place, though very slowly, even when the solution contains enough free ammonia to give it a distinct smell.

With the precautions indicated, ammonium persulphate is a most valuable agent for reducing the printing contrasts of negatives, and by its aid useful negatives can be obtained when, from under-exposure or other causes, the contrasts in the original negative are so great that it is unserviceable.

One point, in conclusion, when ammonium persulphate or sulphate of cerium peroxide, or, in fact, any other reducer which acts by oxidation is employed, it is important to use water which is quite free from chlorides for diluting the reducer and for the final preliminary soaking of the negative. If chlorides are present, the silver of the image, instead of being dissolved as it should be, is partially converted into the chloride, and the amount of reduction is less than it should be, and may be almost nil. In such cases, the image that is left is nearly white. If, however, it is treated with any ordinary developer, it is again reduced to metallic silver, and the reduction process can be started again.

I have dealt only in this communication with the methods that I have found the most generally useful, and I hope that these notes may help some photographic record workers to improve and render more serviceable some of the unsatisfactory negatives that fall to the lot of all of us.

C. H. BOTHAMLEY, M.Sc., F.I.C.

## AND EXHIBITION.

most interesting exhibit is that of the Platinotype Co., which occupied a large stall and an adjoining apartment which had been converted, by aid of the most tasteful decoration, into a studio and gallery. On the walls the company had brought together a very varied and striking collection of professional portraiture printed in

platinotype. The exhibits must have been of special interest to professional men from the different modes of application of the platinum process by such firms and workers as Lafayette, Sala Abus (photographer to the Czar of Russia), H. Jenkins (Lowestoft), T. C. Turner and Co. (Hull), R. W. Robinson (Redhill), Henry Spink (of Brighton), W. Crooke (Edinburgh), The Stereoscopic Co. (London), Martin Jaolette (Kensington), Fred Hollyer, Benque and Kindermann (Hamburg), Albert Coe and Edwin Hadley (Nottingham). Of these photographers, all showing exceedingly fine work, mention may be made of some of Mr. Jenkins' shipping photographs at Lowestoft, and of the portraits of Mr. Hadley, whose name is not, perhaps, widely known, but whose work is in the front rank. Some very fine professional work in platinotype is shown by the Americans, Garo (of Boston), Steffings, Clarke, Knaff Bros. and Philips (of Philadelphia).

But the great attraction at the Platinotype Co. was a new platinum paper yielding sepia prints of a semi-glossy surface of a kind equal to carton at its best. These so-called "Japine" papers are developed either warm or cold, and the extreme beauty of the rendering (especially of the deepest shadows) evidently qualify them for a large share of the printing where quality is of the highest importance.

Colour photography found one attractive exponent in the firm of Fuerst Bros., at whose stall the pinatype process was demonstrated.

Messrs. J. H. Dallmeyer, Ltd., made a good show of cameras, "Adon" lenses, and other apparatus; and their neighbours, the Lumière N. A. Co. exhibited prints and three-colour results on Lumière products. Messrs. Photolinol, Ltd., brought together a fine

collection of prints on the "Angelo" cold development sepia platinotype paper, showing a number of very delicate vignette effects on this paper, and a good deal of striking work on the "Photolinol" sensitized linen. In the gallery, the firm had erected a complete studio fitted with the Cooper-Hewitt light, demonstrations of which were given by Mr. Adolph Langfrier, of whose work with this light a large collection was shown. The Photolinol Co., it may be stated, are sole sale agents (to photographers) for the Westinghouse Co.

Demonstrations of Mr. Manly's process of "Ozobrome," by the inventor, secured interested audiences, and the general opinion was expressed that the process possesses the very greatest promise for professional and amateur photographers.

The Kodak Co. made a representative show of their manufactures, and conducted frequent demonstrations of machine development and other processes. Though not a large exhibit, the company showed some very fine photography in the shape of bromide enlargements.

Carbon printing in excelsis formed the Autotype Co.'s exhibit, by whom demonstrations were conducted at intervals, not only of ordinary carbon pure and simple, but of three-colour printing by the carbon process.

Messrs. Griffin showed and demonstrated the ease and facilities of "Goldona," and exhibited a number of excellent results tastefully arranged as a panel.

"Mattos" paper was similarly treated by Mr. P. L. Thornton, and by Messrs. Wellington and Ward for their several bromide and printing-out papers.

## PAPERS AND

On Tuesday evening, on the return of Conventioners from the Isle of Wight, Colonel S. C. M. Grant read a paper on the photo-mechanical methods employed in the Ordnance Survey, and a paper, prepared on "Old English Manners and Customs," by Sir Benjamin Stone, was read, in his unavoidable absence, by H. Snowden Ward.

The invitation of the Hereford Photographic Society for 1907 was accepted, and Mr. Alfred Watkins was chosen as president.

On Wednesday, the official group was taken by Mr. Max Mills, to whose kindness and promptitude we owe our ability to present it with this issue of the "British Journal" within twenty-four hours

## EXCURSIONS.

of the exposure being made. The key to the group will be given next week.

The Wednesday afternoon's "At Home" of the President, on board the "Duchess of Kent," down Southampton Water, did not belie the enjoyable anticipations entertained in regard to it, and we must congratulate both Mr. Humphery on originating such a delightful excursion, and those members of the Convention who were able to take part in it.

The remainder of the proceedings will be reported in our issue of next week.

## STUDIO BLINDS.

We presume that no photographer will contradict the statement "that some means of controlling the light in the studio is absolutely necessary if artistic work is aimed at." At the same time, there is a great deal of controversy with regard to the handiest and most effective method of securing this control. It is not for us to make any egotistical statement as to which is the best system, but the photographer can settle that to his own satisfaction. We wish merely to draw notice to what one might almost term obvious conclusions.

Some operators have a fixed form of light and get slightly varying effects by altering the position of the figure. The idea is good, since unnecessary and apparently aimless alteration of numerous blinds is apt to discompose the sitter, though we know this is done in some cheap studios to impress customers that the photographer earns his money. In the hands of incompetent and lazy operators, however, this method meets with much abuse, the blinds being untouched, not out of consideration for the sitter's expression, but because once obtained a standard and undistinctive light that neither spoils nor yet appreciably improves the sitter, reduces ignorant mistakes on the one hand, or undue exertion on the other, to a minimum.

By moving the sitter in a fair-sized studio many different effects can be obtained, but usually success will be more easily gained if some independent method of controlling the intensity, direction, or position of the light is available. If one does not wish to use blinds close to the glass that exclude light from all the studio, or perhaps prefers the control to be obtained without moving far from the sitter, a head screen or side screen can be used. Both these accessories are apparently used more in America than in Great Britain, some American photographers getting very fine effects with the head screen alone, and using it practically exclusively.

This head screen, in its usual form, is a ring of about three feet in diameter covered with some translucent material and fixed to a

stand in such a manner that the screen can be held in a horizontal position and raised or lowered, the stand itself being outside the field of view. Since the head rest is practically obsolete, an old head-rest stand could be used for this screen, it having the necessary adjustments for raising and lowering as well as a grip to hold the iron rod, which should be fixed to the screen itself. The ring may well be a child's hoop covered with tracing paper or butter muslin.

The method of using is obvious. For flat faces with little shadow under the eyes the screen should be well away from the head. Gradually lowering we find the shadows under the eyes grow softer and softer until when within a foot of the head even the eye sockets of the very aged are lustrous and full of detail.

### Side Screens.

The side screen is almost purely an American innovation. The advantage is that the operator has almost entire control of light whilst standing within a yard or so of his sitter, so that he is in a position to note every change.

These screens can be made extremely elaborate, but a good all-round one is made as follows:—There are two uprights, about eight feet high, fitted with bosses and castors. These are separated by four pairs of brass-covered iron rods about eight feet long, and almost equidistant apart, the whole thing much resembling a clothes horse. The pairs being at the same height from the floor, but separated by the width of the uprights from one another. On the four rods on one side are hung eight short curtains of thick opaque material, and of a width an inch or two greater than the distance separating the lower from the higher rods. There are two curtains to each rod, and each curtain should be wide enough to have some fullness when both are drawn out. The four rods on the other side are supplied with exactly similar curtains but of white transparent material. The use of these

tain is obvious; strong light is obtained from any direction by the black curtains only. The light can be softened and diffused by using the other curtains. Of course, smaller screens and different dimensions are very common, but unless one also uses blinds of glass a smaller arrangement than the one described is not to be recommended.

These methods of controlling light have their devotees, but, generally, we think they fail since it is totally impossible to exclude all direct light: some diffused light must find its way round the blinds, and we believe that for really fine lighting the precept of the masters "that light must come from only one source," should be followed.

### System of Fixing Blinds.

Diffusion or softness of lighting as well as strong contrast effects obtained by altering the size and position of this one source of light rather than using reflectors or diffusing the light through different media. To follow this method the studio must be supplied with blinds that will exclude every trace of light but that coming from the necessary position. To do this the blinds must be quite opaque and as close to the glass as is possible.

There are several ways of fixing material in this position. The most usual, though not, we think, the best, is the roller-blind system; long lengths of blind material, usually of the same width as the blinds, being fixed to one of the many makes of spring roller on the market. When the blind is drawn down the turning of the roller tightens a spring, which, when the resistance is removed from the blind, re-rolls it. We do not suppose that now that rollers are so cheap anybody will wish to make their own, but it may be of interest to recollect the late H. P. Robinson's advocacy of blinds worked by weights as being most reliable. The weights being lifted when the blind was pulled down, force of gravity re-rolled the blind. If the weights can be hung out of sight, say, between the wall and a casing, the simplicity of the method may even now recommend it. In an issue of the "Almanac," about 1872, one writer described a roller-blind of a cheap character. In place of the spring he used a sort of bobbin fixed to the end of the roller to which blind is attached, and round this wound some circular elastic about an eighth of an inch in diameter, similar, we believe, to that used by youthful dilettantes for that weapon of annoyance known as a "catty." The rolling of the blind wound the elastic round the bobbin, causing enough tension, to automatically re-roll the material, when released. Intransparent, as well as opaque blinds can, of course, be used in this system.

This system has, however, several disadvantages. There must be a means of controlling the height and position of light is to be adequately controlled, a means of blinds rolling from bottom of light as well as blinds working from the ridge; this introduces great complexity in working, and the numerous cords are very annoying. The blinds will certainly sag if allowed light to enter studio where not required, unless some means of preventing it is devised. The best way is to fix parallel to glass, a few inches below it, two taut wires for each blind. The blind then rests on the wires instead of sagging in the studio.

### Hanging Blinds from Wires.

All this, however, makes for difficulty in working, and there is another system, though very sparsely used, yet more satisfactory in every way.

For this system taut wires are stretched across the studio, and the blinds hang from a ridge to eave. These wires should be a distance apart equal to the width of the material one intends to use, allowing, of course, a little for fullness and hemming. A distance of thirty-six inches is very useful. The lowest wire should be about three inches below the bottom of the glass of skylight. The second will then be thirty-six inches above that and quite close to glass; the third should now be placed rather further from glass than the second, and three or four inches below the second wire. This is to allow the blinds to overlap, the first blind being fixed by rings at its outer edges between the first two wires. The other curtains, as many as required, being fixed between wires also, but with their edges overlapping a few inches their neighbours. As many blinds as will quite cover the glass are required. Sufficient control will not be obtained, however, by having only one long blind on each pair of wires, the necessary length, allow-

ing for a little fullness, should be divided into at least two or preferably three parts. The rings fixing the curtains to wire should be fixed on blinds at a distance of every three inches, say, before the wires are stretched, as this is much more simple than placing a number of rings on wire, and stitching material to them when up. The wire should be of brass. Iron-wire rusts and prevents the rings moving freely, whilst owing to the elastic nature of copper it is impossible to stretch a wire of this material to anything like the

requisite degree of tautness. Some methods of stretching the wire and of tightening it when necessary must be provided. The old key working a drum and ratchet wheel similar to the stretching post of a wire fence are no longer generally used. A better method is to obtain galvanised iron or brass lanyards from a yacht fitter's; those with four-inch screw will be big enough.

To stretch the wire fix in a strong screw eye at one end of studio and fasten one end of wire to this, thread lower edge of curtain on to it, and then pass through the bight of lanyard, placing the hook end of latter in another screw eye. The screw of the stretcher should be almost out of the socket. Enough wire must be left with which to get a good purchase. Get someone to tightly stretch the wire between screw-eye and lanyard by pulling wire through the eye

of the latter. When no further exertion will obtain a greater degree of tautness, with a pair of pliers give the wire a turn to temporarily secure it, cut off superfluous end, and finish off the join. A few turns on the lanyard will further tighten the wire, but this should be kept as a reserve force for use when the wire slackens and sags with use.

To move these blinds from place to place a short bamboo pole of about 6 feet long may be used, and as will be easily seen, an opening for light of any size whatsoever can most easily be obtained by sliding the blinds on these wires much more easily and quickly than by the old method of spring rollers, when, perhaps, eight or more cords would have to be removed from cleats, tightened or released, and again cleated before result could be obtained. With this newer method absolutely any light can be obtained in three or four seconds and with very few movements.

Personally, we believe the need of the bamboo pole has frightened photographers off this method, though really we have used the old method for many years, and the new for three, and under no circumstances whatever would we go back to the old system, the other being so much more rapid, efficient, and easy to work. The pole is quite small and does not get in the way at all.

### Glass for the Studio.

Another question appertaining to the studio light is the kind of glass to be used, whether plain, sheet, ground glass, or ribbed.

This last must, of course, have the ribs inside the studio, and is an extremely good diffuser. It suffers, however, in common with ground glass in that, whilst in the summer the light is properly softened, yet in the dull days of winter the quantity of light admitted cannot be increased. For this reason, and also because of its cheapness and the ease of replacement, we prefer ordinary sheet glass. In summer this is covered with tissue paper, which in the winter months, when the clouds and thick atmosphere act as too effective diffusing agents, we remove, and are thus able to gain an exposure of frequently less than a second at  $f/6$  during the worst winter months. The putting on of the tissue paper which must be of the best quality is a most simple operation, though doubtless those who have not tried the method will think it a dirty and troublesome makeshift.

The simplest way to apply the tissue after cleaning glass is first cut tissue about two inches wider than the distance between sash bars, then beginning at the ridge run a starch brush full of stiff starch down the angle where glass joins sash; this should just starch a strip about half an inch wide of glass and sash. Do the two bars for a depth equal to tissue to be applied, and then lay tissue on to glass, and smooth out to the edges. The light paper will stick to the narrow strip of starch, but a small dab should be placed in centre top and bottom. The next sheet should overlap the upper one about half-an-inch. When the tissue is to be removed very little energy is required, so very little adhesive being used. A damp sponge will do the trick in a few seconds.

W. FOSTER BRIGHAM.

## THE FAULTS OF A LENS.

DR. W. SCHEFFER, in "Photographische Randschau," describes a number of simple experiments which will instruct the beginner in studying the optics of the photographic lens. As a rule photographic optics are unfortunately a sealed book to the average amateur. Most articles and books in which such subjects are treated of, assume some previous knowledge, and the means of obtaining a clear understand-

Fig. 1.

Fig. 2.

ing by experiment are wanting as a rule in the amateur's outfit. The following experiments may be performed with very simple and readily obtainable means, and yet give a very clear explanation of some of the important facts of photographic optics.

For the experiments we require a bellows camera, black paper, cobbler's wax, and a single uncorrected lens of the reading glass type. The latter can be very easily obtained. In optical factories many lenses are rejected on account of small faults; for instance, a small

Fig. 3.

Fig. 4.

piece is chipped out of the edge and so on. The focus of this lens should not be too short, from 4 to 8 inches, and the diameter not too small.

The subject to be taken we can make out of a piece of ground glass and some pieces of black paper. The necessary figures are cut out of black paper and stuck on the smooth side of the ground glass. If one has no ground glass, an unexposed dry-plate may be taken or a piece of thin white paper, as free from structure as possible may be put behind a sheet of clear glass. The lens should be fastened with the wax to the front of the camera, and in order to stop out stray light a piece of black paper with a circular aperture of somewhat

smaller diameter than the lens should be placed in front of it. Of course, the lens must be arranged so that its optical axis is at right angles to the ground glass. It should be noted that the cobbler's wax will not injure the camera; it can be easily removed with a dry, warm flannel.

The first test object should be a cross, cut out of black paper, and

Fig. 5.

attached, as already stated, to the glass. The camera is now set up so that the middle of the cross is as near as possible exactly on the optical axis of the lens. It is advisable to cut the cross quite small and to make its arms as thin as possible; the distance from the lens should be about equal to its focus, and the image should be examined with an eye-piece, or enlargements made from the negatives. The illustrations to this article were made in the latter way.

Fig. 6.

Fig. 7.

Behind the ground glass should be placed a light, and then a sharp image should be tried for on the focussing screen. It will be found that this is not possible, for the image appears indistinct and almost unrecognisable; if the aperture of the lens is large enough, as shown in Fig. 1. Obviously, Fig. 1 is obtained by using the full aperture of the lens. Now let us insert a stop or diaphragm by placing in front of the lens a piece of black paper with a circular aperture of about two-fifths of an inch diameter. This stop should be placed exactly over the centre of the lens, so that the optical axis passes through the centre of the stop. The cross should be again focussed sharply, and the image of the cross is distinctly seen in the middle of the figure, surrounded by a bright halo, Fig. 2.

We can now see whether the axis of the lens is at right angles to the focussing screen, and whether the centre of the cross is on the optical axis. Only when these requirements are fulfilled does the bright halo symmetrically surround the brighter cross. If the halo is unsymmetrical, the lens should be shifted and affixed afresh, or the test object shifted to and fro till the image is seen, as in Fig. 2.

Fig. 8.

Now insert a small stop of about one-twelfth of an inch diameter, as before, in front of our lens. The image of the cross will now be sharp, as in Fig. 3. Thus we have proved that a small part of our lens, in the case in point, the centre can give a sharp image. This image becomes fuzzy when the margins of the lens also act and the full aperture produces the images. Fig. 4 shows why this happens.

Fig. 9.

Now let us make a diaphragm with two apertures, the one central, but the other nearer the edge of the lens. Each aperture should have a diameter of a twelfth to an eighth of an inch. When, with the lens thus stopped down, we try to focus the cross we see on the focussing screen two images of the cross, and by covering the central or marginal aperture easily determine which image is formed by the

Fig. 10.

central and which by the marginal rays. We shall see that when the former is sharp the latter is not, and vice versa. Each image can be sharply focussed alone, but not the two together. The image thrown by the marginal rays is nearer the lens than that formed by the central rays. Moreover, the two have different positions as regards the optical axis. The image given by the marginal rays does not lie on

the optical axis but to the side of it on which is the aperture in the diaphragm. We thus see why the image given by the full aperture of the lens is fuzzy, and that the different smallest parts of the lens project images, each of which by itself is sharp, but these images lie in different planes. We cannot therefore sharply focus all at once, but we obtain under all conditions a fuzzy image, as shown in Fig. 1. This phenomenon is due to the fact that the lens is bounded by spherical surfaces. After this experiment the diagram in Fig. 5 can be easily grasped without further explanation.

Want of achromatism, or the non-correction for colour, can be also very easily explained by our arrangement. We merely have to take a red and a blue glass, and place first the red and then the blue between the source of light and the ground glass, and focus sharply

Fig. 11.

with the stop as used for Fig. 5. We shall at once see that the blue image lies nearer the lens than the red.

Now let us displace the test object, and place to one side of the optical axis. Place centrally in front of the lens the small stop, one-twelfth to one-eighth of an inch diameter. When now the two arms of the cross are focussed it will be found that they cannot both be made sharp at the same time; either the vertical or horizontal arms will be sharp. The two planes of sharp focus are situated at different distances from the lens. Figs. 6 and 7 show this phenomenon. Thus the amateur can very easily obtain an idea of what astigmatism is.

By the aid of a circular piece of cardboard and a few threads, these facts can be very easily grasped. Let us cut a circle of cardboard,

Fig. 12.

Fig. 13.

and pierce the same with five small holes, as shown in Fig. 8. In the middle, M, let us place a thread of a distinct colour, white for instance; through A and B let us draw red threads, and through C and D two blue threads. Now let all the threads be brought together to a point, so that the middle thread, M, lies in the plane of C D, but not central with the centre hole, yet at right angles to the cardboard, then obviously the threads passing through C and D are in a different position as regards the lens to those passing through A and B.

If instead of the cross we place on the sheet of ground glass a piece of black paper with a small round hole in it, we shall find on trying to focus this hole, that we obtain a peculiar cruciform image, and, according as the focussing screen is moved to and fro, will the vertical or horizontal arms of this cross be the sharper. This

phenomenon is called astigmatism. Our experiments are better than all drawings, and give a very clear conception of this fault.

We also see that the phenomenon of astigmatism is not affected by stopping down: it appears with very small apertures very distinctly. If the image of our point-like test object is formed with full aperture, we obtain an image as shown in Fig. 9. In order to make the occurrence of this phenomenon quite clear, we must use the two apertured diaphragm as with Fig. 4. We shall see that the different parts of the lens also beyond the axis shown spherical aberration. Each individual small aperture projects an image of the point which lies to one side, which image is accompanied by astigmatism, but is still sharper than that projected by the full aperture of the lens. This phenomenon, the spherical aberration of oblique rays, is known as coma, and is lessened by stopping down, but astigmatism is not.

Distortion can also be made very clear with our arrangement. We merely take an object bounded by straight lines such as a window, first with a small centre stop in front of the lens, and then with the same behind the lens. Fig. 10 shows the barrel shaped distortion,

with the stop in front; Fig. 11 the cushion-shaped distortion with the stop behind.

Figs. 12 and 13 explain this; as the result of the prismatic deviation of the pencil of rays by the marginal portions of the lens the position of the object point of the middle of the image must be reproduced too small, and this fault must be more noticeable the further the object point lies from the middle. Fig. 13 shows that just the opposite occurs with the stop behind.

These simple experiments can be performed by anyone without any previous knowledge. With a little sound and common sense conclusions can be drawn from the experiments, and a clear understanding of the principal points in photographic optics be obtained. Obviously these experiments may be carried still further and made more interesting. Here only a few simple exercises have been described, and only the most obvious conclusions pointed out, it being borne in mind throughout that even these few may be too much for some amateurs, or, at least, ought to be sufficient for a fairly long evening's entertainment.

## METHODS FOR THE RAPID DRYING OF GELATINE FILMS AND NEGATIVES.

The following notes, by Dr. Roenius, in the "Deutsche Photographen Zeitung," are of interest not only in the face of the fact that every photographer occasionally wishes to rapidly dry a negative or print, but more so now that some have adopted the method of colour-sensitising their own plates, and the quality of plates thus sensitised depends to some extent on their rapid drying.

Gelatine in the dry form is a hard, brittle substance, which swells up in water and gradually assumes a pasty form. At about 50deg. F. the swollen gelatine becomes gelatinous, and at about 77deg. F. a thick liquid, which, with increasing temperature, becomes quite fluid. On cooling the gelatine again reverts to a jelly, and then slowly dries. If the gelatine is repeatedly and continuously boiled, it loses some of its original properties and remains fluid for a long time—that is to say, it loses some of the water it has taken up, and is then much heavier than fresh gelatine. This property of a gelatine mass has been used technically, as in the so-called hectograph mixtures, in which a superior kind of glue or inferior gelatine is melted with some glycerine and water, and by continued boiling forms a comparatively stable damp mass. With certain kinds of glue some baryta is added to make the mass insensitive to damp.

Through the action of tanning substances, such as tannin, alum, formaline, etc., the gelatine is submitted to an astringent action—that is to say, its pores contract, and it is reduced in volume.

In order to dry gelatine emulsions on plates and papers, a good current of air should be used to carry away surface moisture, so that that lying underneath may escape to the top, and be carried off until the film is dry. If the film has not been hardened, the temperature should not be raised above 68deg. F., as otherwise the gelatine may run, as has sometimes been experienced by photographers who have placed wet negatives in the sun or near a fire, a phenomenon which is sometimes used with intention to produce the so-called photographic caricatures.

### Drying With Volatile Liquids.

The principle of this method is to mix the water with a liquid which is more volatile and thus hasten the drying. Of all the volatile liquors, pure alcohol can alone be recommended; methylated spirit is less satisfactory, as the fusel oil, etc., which it contains has an unpleasant smell (and the spirit obtainable in this country does not give a clear surface to the negative.—Eds. B.J.P.). Small plates should be bathed in 60 per cent. alcohol, and the latter should be about one-fifth of an inch over the plate; in a short time the alcohol extracts the water from the film. If the plate is now exposed to the air, the semi-spirituous water in the film evaporates more quickly. Obviously for large plates diluted alcohol should be used, otherwise with such large surfaces exposed to the air the alcohol evaporates so rapidly that the process costs more than it is worth.

### The Use of Hygroscopic Substances.

By this is meant the use of exsiccating substances as employed in practical chemistry. The hygroscopic substances are sulphuric acid, calcium chloride, and potassium carbonate. For photographic work fresh fused calcium chloride is the best. A large box should be made of millboard, or, better, sheet zinc, which should be quite airtight; the calcium chloride should be strewn over the bottom of the box either in the form of powder or small lumps. The plates to be dried should be first well drained (their backs also wiped dry), placed a few inches above the calcium chloride in racks, and then the lid shut down; the closer the lid fits the better the exsiccator acts. The dry, freshly-fused calcium chloride extracts the whole of the moisture from the air, and this then rapidly extracts the water from the film. The whole method is very simple, but it is not very rapid in comparison with other processes.

### Drying by Means of Heat.

For more than ten years drying boxes of wood or metal with perforated bottoms and partitions have been in use. Circulation of the air is effected either by means of a spirit lamp burning in a bent pipe or by means of a revolving fan. We have thus a method of heating the air or a mechanically produced draught, to which we shall refer later.

Although such arrangements may be useful in factories, they are not exactly practical for a studio where plates are not commercially manufactured. We have also met with plates which must not be dried at a moderately increased temperature.

If a well-washed negative is bathed, however, in a bath of one part of formaline to eleven parts of water for eight or ten minutes, the gelatine is so hardened that it will stand three times the amount of heat, even up to 120-140deg. F. For such plates any drying oven with heating arrangement may be used. Still even then the plates ought not to be heated too suddenly, but gradually. It is as well not to be too optimistic of this method, as it is neither the best nor shortest.

### Drying by Mechanical Movement.

There are two methods of effecting this: 1. Either the plate to be dried is whirled rapidly round in the air, or (2) the plate remains still, and (a) either the air is driven straight over the surface to be dried by straight-bladed paddles, or (b) rotating propeller fans suck up the air and drive it through a perforated cone on to the plate.

The first arrangement is the older. In this the plate to be dried is fastened by means of adjustable nuts on three or four arms radiating from a central axis round which they rotate. Drying by this method means a saving of time of from 45 to 85 per cent.

the only disadvantage of this process is that for large plates the apparatus is so large and complicated that it is not practicable.

By the second system, in which the object remains still and a strong stream of air is directed over it, any sized plates can be dried, and there is no danger of the plates breaking, which may sometimes happen with the other processes.

Fans rotating at about 230 to 650 revolutions per minute with suitable machine driving are the best, and for hand work a multiplying or transmission wheel is essential. The blades of the fan should be placed diagonally, and at about an angle of 20deg., to obtain the strongest draught. The blades should be of Bessemer steel, and firmly welded to the shaft, or else screwed with four or eight bolts. There is then not much danger of fracture and the blades working loose, as the revolution is not fast enough. Electric power the best, and a small dynamo will suffice, but this taking it out of the hole will not be found to be the cheapest system, but will be the nicest.

[The author's review is evidently intended for those contemplating the adoption of regular means of drying plates. Mention, however, might have been made of a simple and expeditious plan which is often of service in emergencies, and consists only in dabbing the gelatine film of a large proportion of its moisture by the application to it of a piece of fine soft cambric (an old pocket handkerchief), which is pressed into contact with a roller squeegee. The film thus gives up a good deal of its moisture, and on placing in a warm, airy spot will dry in under an hour; or if stood about a foot distant from an electric fan, so that the current of air passes slantwise over it, in a few minutes.—Ebs. B.J.P.]

#### HINTS ON PHOTOGRAPHING CHILDREN.

THERE is no branch of photography that is more interesting or better adapted for the home study of the amateur than the photographing of children. At the same time there are few subjects that are more difficult to handle. The first essential (writes Ruth F. Manly, in the "American Amateur Photographer") is to get on good terms with the subject if it is a stranger, then, if you can keep them interested and let them pose themselves, you will be sure of getting pictures that are natural and do not possess that over-conscious look so general in the portraits of grown-up people. It is usually important to arrange all the accessories before you place your subject. It is annoying even to adults to be shifted and turned and twisted before the camera. A good plan is to focus on some other object in the position the child is to occupy, and when ready to snap up a flow of conversation and induce the little one to occupy the desired position—then watch your opportunity and press the bulb. It is sometimes necessary to do a little posing, but do not weary them by making them hold strained positions for any length of time, and as a rule it is better to let them take their own positions.

Another thing which needs consideration is the matter of dress. Pictures of over-dressed children are seldom satisfactory, and while a mother may like to see it dressed in frills and ribbons, the something which they are accustomed to wear in their play will, as a rule, yield the picture which will be prized the most. A plain background should be chosen, unless they are to be photographed among their toys and in a portion of a room, when any chairs or other objects should be removed. Lower the camera until the lens is as near as possible on a level with the face, and if the attention of the child is directed to any object, that object should also be held or placed on a level with the camera. The reason for this will be apparent if you focus on a person who is looking direct at the camera and then ask them to look at an object a few feet higher, when the change of position of the eyes will give a totally different expression.

Children should not be photographed in a strong direct light, as it tends to harshness. If the sitter is near a window, muslin or tissue paper should be used to diffuse the light and a reflector used to give tone to the shadows. The full opening of the lens should be used and full bulb exposure given according to the strength of the light and the stillness of the subject. For this kind of work only the fastest plates should be used, and when you have a good subject and every-

thing is in working order, do not be stingy with the plates. Use a weak developer, and do not force the development after the high lights show on the glass side, and you will avoid the harshness which is so commonly seen in indoor work.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been made for Patents from June 25 to 30:—

STANDS.—No. 14,553. Improvements in stands for photographs, calendars, or the like. Robert Christopher Rogers, 48, Corporation Street, Birmingham.

PRINTING FRAMES.—No. 14,594. Improvements in the production of photographic prints and in printing frames therefor. Peter Wright, 55, Chancery Lane, London.

SQUEEGEES.—No. 14,863. Improvements in squeegees more particularly applicable for photographic purposes. The Thornton-Pickard Manufacturing Company, Ltd., George Arthur Pickard and Frank Slinger, 6, Bank Street, Manchester.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

FILM STORAGE DEVICE.—No. 12,029, 1905. The invention is designed to facilitate the storage of film negatives. A rigid pocket or holder of cardboard, or other suitable material on which a sheet of paper is pasted so as to form, as it were, a flapless envelope, is made. The cardboard projects above the top of the paper flap for the purpose of providing a space for affixing consecutive numbers, and the title and data of contents of the holder. A thumb space is made in the top side of paper flap to enable the film negative to be grasped when removing it from its holder, which can be readily done by separating the cardboard and paper flap by slight pressure on the ends of the holder, thereby causing the said parts to bow outwards. Percy Gerald Reynill Wright and Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

## New Books.

"The Year Book of Photography." Edited by F. J. Mortimer, F.R.P.S. London: "The Photographic News" Office. 1s.

On its first appearance under Mr. Mortimer's editorship the "Year Book" exhibits certain changes in arrangement, made with the object of constituting this year's issue a convenient guide to the modern printing processes. The contributed articles deal with the processes at present popular, M. Demachy writing on gum, Mr. H. W. Bennett on carbon, and Mr. E. J. Wall on P.O.P., plain salted paper, and albumen. Mr. Walter Benington deals with platinotype, Mr. G. E. H. Rawlins with the oil process, and Mr. Manly with ozotype. The editorial article has bromide and gas-light papers for its subjects. Following each section are the formulæ generally adopted, and those recommended by individual makers for their papers, and the whole of the matter on a given subject is thus found in one sequence of pages. The arrangement is convenient in the present instance, though it may be doubted whether the regular purchasers of an annual publication, to which they have been accustomed to turn when looking up a formulae or table, will welcome any disturbance of the contents plan. Nevertheless, as it stands, the "Year Book" provides a very handy con-

spectus of the present methods of printing as they may be commended to the amateur photographer. The lion's share of the space goes to the editorial compilation on the development papers. The value of the latter in our estimation would have been increased had extracts from other writers been acknowledged. The omission to credit a source of information is an injustice to the reader, as it robs him of the opportunity to pursue his study of the subject, and it appears quite inexcusable when whole passages appear as editorial contributions. The "Year Book" contains an excellent directory of photographic societies, and a number of very good plate illustrations bearing on the articles.

"Natural Colour Photography," by Dr. E. König, translated by E. J. Wall, F.R.P.S. (Dawbarn and Ward.) 2s.

The translator, in his preface, states that never within the last twenty years has there been so much interest displayed by photographers generally in photography in natural colours, as at the present time, a statement which probably will not be denied, and that this is due in a great measure to the most recent advances in colour sensitising must also be accepted. This work is described as "a practical guide to the various colour processes that can be adopted by amateurs and others," and it fairly fulfils its promise. But brief notes are given of the Becquerel and Lippmann, Joly, Lumière starch grain, and the Prof. Wood's diffraction process, the bulk of the book being devoted to the indirect methods, which naturally have more interest for the average worker. After a brief note as to the apparatus and the positions of the filters, the preparation of the latter is most fully described, and the sensitising of the plates with which they should be used. The various methods of printing, both for lantern slides and prints on paper, are fully described, and the latest formulæ are given. Lumière, Sanger-Shepherd, Pinatype, are all treated of at length. Considerable attention is paid to the optical synthesis method by projection, and chromoscope, and working instructions are given for making the latter instrument. The work will be found an excellent practical guide to those processes which may be adopted for making photographs in colours exclusive of photomechanical methods, and there is but little theory or historical data, and it is written in simple language.

"La Photographie des Couleurs" is the title of a new monthly magazine, edited by M. H. Quentin, and published by Chas. Mendel, 118, Rue d'Assas, Paris, which, as its title shows, is to devote its attention solely to the subject of natural-colour photography. The first number promises well, and the illustration is decidedly successful.

## New Materials.

EDWARDS' Iso Plates.—The recent re-establishment of the old firm of B. J. Edwards, now with its founder, Mr. B. J. Edwards, at the head, is a sufficient reason for our receiving some time ago some samples of the firm's present issue of the "Snapshot Iso" plates, a manufacture which becomes particularly noteworthy in these days of colour-correction from the fact that Mr. Edwards was the first maker of isochromatic plates in this country. If for a time the Edwards plates fell, if not into disrepute, at any rate into disuse, their originator could not be held responsible, but on his re-accession to the technical management of the factory, it is evident that the plate—we are speaking now of the "Snapshot Iso,"—shows itself capable of the high favour which has been extended to it by skilled photographers in the past. Sensitometrically, we have not found the plate to run out to a high figure, and we confess, to some astonishment, at the excellent results obtainable on it with rapid exposures in a hand-camera. However, the laboratory test of speed alone does not completely account for the properties of a plate, and in one respect particularly—keeping powers—our experience of the Edwards plate has been altogether excellent, and we believe that has been the general opinion of them. The firm itself have recently come across some examples of good keeping in some Iso films exposed over ten years ago, and productive of excellent negatives. Their finding, as we have said, is not at all exceptional, and for this and other reasons arrived at after some recent considerable experience with the plates as now issued, we may congratulate them on their manufactures.

## New Apparatus, &c.

The Zeiss "Stereo-Palms." Made by Carl Zeiss, Jena. (London, 29, Margaret Street, W.)

When we reviewed the "Universal Palms" hand camera in January last, we commented on the beauty of mechanical construction through which the manipulation acquired an ease and certainty only to be met with in the perfect adjustment of the working parts of any machine. The same may be said of the "Stereo-Palms," which is similarly a folding camera for use on hand or stand. Instead of the four-strut extension of its predecessor, the "Stereo" camera racks out on the baseboard-cover of the front, which latter is provided with two focussing scales permitting the use of the camera for its three purposes of:—

- (1) Stereoscopic work with a pair of lenses of  $3\frac{1}{2}$  in. focal length;
- (2) Panoramic work with a lens of  $3\frac{1}{2}$  in. focal length used to cover the whole  $9 \times 12$  cm. plate after stopping down;

- (3) Instantaneous work at the normal angle represented by a lens of  $5\frac{1}{2}$  in. focal length on the whole  $9 \text{ cm. by } 12 \text{ cm.}$  plate.

The lens panel is mounted so as to be instantly detachable on loosening the clamping bar on the right. One of the lenses is also removable and is transferred to a shelf or panel when panoramic (wide-angle) work is to be done. Similarly, the  $5\frac{1}{2}$  in. lens (Tessar or Wray) is quickly inserted on its panel for work at the normal angle adopted in hand-camera photography. For these three distinct purposes the camera is equally applicable, the stereoscopic partition rolling up like a spring roller, and being then removed from the back of the camera. In miniature, which appeal only to the photographer as distinguished from the constructor, the camera can show a few nice points. For example, when the camera is carried by its sling handle the dark slide is upside down, the slit admitting the shutter, thus unexposed to direct strong light from the sky. The position makes for light-tightness, though Messrs. Zeiss will perhaps allow us to say that it is an unnecessary one in the case of the "Palms" slides.

The focal plane shutter is the one we have already noticed with outside fit adjustment, permitting with the tension of a range from 1-25th of a second to 1-1000th. In all respects the camera impresses us as perfectly designed and made. It is supplied for simple exposures, for stereoscopic and panoramic pictures, or for all three species of work.

### FORTHCOMING EXHIBITIONS.

- August 6: Andover and D. H.S.—Sec., W. I. Gradidge, Jubilee House, Andover.
- September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.
- September 20 to October 27: Royal Photographic Society.—Sec., J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.
- October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.
- October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.
- November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismire," Stafford Road, Southsea.
- November 20: Sefton Park Photographic Society.—Sec., A. W. Farr, 34, Loudon Grove, Liverpool, S.
- November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.
- December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

News and Notes.

NEWMAN AND GUARDIA.—The question of a correspondent in ference to our paragraph of last week on the death of Mr. Guardia, to the continuance of the firm, has doubtless risen in the minds others, and it may be well, therefore, if we say that, beyond some mporary disarrangement of the business side of the company's airs, Mr. Guardia's death will not affect the output, nor lower e standard of "N. and G." cameras. Mr. Newman, we learn, ill retain his interest in the business, and continue to be respon- sible for the design and production of instruments which have made s name a household word in photography. The "Sybil" pocket mera is expected in a month or two's time from his workshops, prove once more, so we believe, the perfections of camera consti- tion possible to the mechanical craftsman who is also a practical otographer.

THE Longstaff medal of the Chemical Society has been awarded to of. W. N. Hartley, F.R.S., in recognition of his spectrochemical vestigations; the presentation will be made at the first meeting t next session, October 18.

ATTRACTIONS of Cardiff.—The Cardiff Parliamentary Committee et last week to receive the series of photographs of the beauties nd attractions of Cardiff, which had been sent in by the various mpetitors in response to the offer of two prizes of five and three uneas offered by the corporation for the best series of ten pictures lustrative of Cardiff and Llandaf, to be used for the purpose of iversting the attractions of the district in railway carriages and ewhere. The award of the honorary adjudicator, Mr. Samuel llen, was adopted, in accordance with which the first prize was iven to Mr. T. O. Long, 62, Queen Street, and the second to Mr. . R. Taylor, 33, Constellation Street. A sub-committee was ap- ointed to make a selection of the best photos from the whole lot eceived, and to report to the committee.

WINCHESTER Cathedral Fabric Repair Fund.—A lantern lecture ill be given in aid of this fund on Monday, July 16, in St. John's ooms, Winchester, at eight o'clock, entitled "The Pilgrims' Way rom Winchester to Canterbury," by H. Snowden Ward, F.R.P.S., llustrated by lantern pictures prepared especially for this lecture y Mrs. Catharine Weed Ward, F.R.P.S.

THE Barnet Whitsuntide Competition.—Messrs. Elliott and Son, f Barnet, inform us that the following were the successful competi- ors in their Whitsuntide Competition: First, Mr. A. G. Thistleton, f Manchester; second, Mr. Geo. Harley, of Lincoln; third, Mr. larence Ponting, of Scarborough; and fourth, Mr. S. G. Ward, f New Cleethorpes. The average quality of the work was even igher than that entered for their Easter corpetition, and the entries ore. A new competition has also been instituted which will appeal o many who are just now thinking of taking their holidays, for the ubsjects are "Scenes at the Seaside, Views on the Sands or Coast, Seascares, or Children Paddling or Playing on the Sands." One cash prize of two guineas, one cash prize of one guinea, and six prizes f half-a-guinea, for the best prints on any Barnet paper from negatives taken on Barnet, Ortho, or other brand of Barnet Plate or Films, any size, are offered. The latest date for sending in the prints is October 31. In connection with this competition Messrs. Elliott are issuing to dealers an attractive poster and handbills to all dealers, from whom full details may be obtained, or direct from Barnet.

THE Liverpool One Man Shows.—Till the 20th inst. there will be open, at the rooms of the Liverpool Amateur Photographic Associa- tion, an exhibition of the pictorial work of Mr. F. C. Stuart. This will be followed by the work of Mr. Joseph Appleby.

THE Bristol Photographic Club have arranged an exhibition of their Dührkoop's work, as recently shown at the BRITISH JOURNAL OF PHOTOGRAPHY Offices, from July 12 to 19 at the Kensington Government School of Art, Berkeley Square.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
14 .....	Manchester Amat. Photo. Soc.	{ "Photographing Flowers." Demon- strated. Dr. A. T. Lakin.
14 .....	Hackney Photographic Society	Outing to Broxbourne.
14 .....	Aberdeen Photo. Assn. ....	Outing to Black's Dam.
14 .....	Hull Photographic Society ...	Onring to Welton Dale.
14 .....	L.C.C. Staff Camera Club .....	Outing to Oxshott.
16 .....	South London Photo. Society ..	Jumble Sale.
16 .....	Southampton Camera Club .....	{ Print Trimming and Mounting Com- petition.

18 .....	North Middlesex Photo. Soc. ...	Short Papers by Members.
		"Platinotype Printing." E. Salt.

Commercial & Legal Intelligence.

PHOTOGRAPHING Bed Spreads.—Mr. Arthur E. Smith, 8, Farring- don Avenue, sued Messrs. Rheinlander and Co., 141, Rosebery Avenue, for £5 3s. 8d., for photographing bedspreads. The claim was admitted, but the defendants counter-claimed for £2 14s. On the ground that the plaintiff had damaged the bed spreads. The plaintiff said he told the defendants that he did not care about doing the work because it was of such a delicate nature. That was denied. The judge said that if a man accepted a job he must do it properly. He did not think, however, any negligence was proved. It was evidently very difficult. Judgment was entered for the plaintiff on the claim and counter-claim.

AN Obstructionist.—At the Highgate Police Court, on the 5th inst., William Hambley, of Durham Road, Finsbury Park, was ordered to pay 6s. costs on a summons for causing an obstruction at East Finchley with a photographic camera and portable dark-room.

Correspondence.

- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—My letter has aroused more interest than I expected it would. I am not in the habit of airing my grievances, so long as they are only my own, but this question is one which affects photographic assistants as a body. It is one of the very few professions or trades of which the employees are absolutely unprotected. For skilled labour, the wages usually given are contemptibly low. There is no incentive offered to an assistant to cause him to try to improve himself. He may spend his hard-earned money to acquire extra knowledge, but he knows full well that he will get no extra salary. I am afraid there are many employers who take the man who offers to go for least pay, provided his work is at all passable. We know these employers tell the same old tale—viz., that the prices are cut so fine as to make it impossible to give more. But who is to blame for the low prices? It is the greediness of the employer, who thereby hopes to attract more customers. And the assistant has to pay the piper.

"Othello, M.P.P.A.," in his letter, says, "I am mistaken in my re- marks." I am sorry to contradict "Othello," but I know I am right. I do not say there are a majority of "backyard studio" men in the

P.P.A., but I do know there are several such men who remain in, not for the help of their fellow professionals, but simply because they get a reflected respectability from the association by means of putting M.P.P.A. after their names on their mounts, notepaper, etc. In an artisan community this is a decided acquisition, as it gives the ignorant the idea that the man has passed some examination. I have often been asked what these letters mean, and when I have explained they have said, "Oh! is that all; I thought it was some degree."

These "amateur professionals" know this very well, hence their willingness to pay the 5s. per year. It is worth more than £5 to them. I would like to see the P.P.A. make this title a mark of ability in a similar way to the "Royal." And I would like to see them introduce examinations for assistants and give certificates showing forth that the owner is capable of doing such work as he or she professes to be able to do. This would do away with another bugbear of the assistant's life—viz., specimens. Specimens are a continual bother to everyone. They are a big item to an assistant, as they are continually being kept by even respectable houses. Besides this, specimens are no guarantee that the assistant can do similar work, as, I am sorry to say, there are certain unscrupulous men who make use of others' work. Where is the guarantee that they have done the work?

I would be one of the first to sit for an exam. under such conditions. But I shall certainly not go in for a P.P.A. certificate under the present conditions. It is silly, on the face of it, for the testimonials of past employers have the same effect.

"Another Assistant" says truly that the assistants could do much to put down some of the rogues done under the name of photography. They could also very much improve their employer's business if they were treated rightly. But they are usually treated merely as "hands," hence their indifference.—Yours etc.,

DISGUSTED ASSISTANT.

#### To the Editors.

Gentlemen,—Having read with interest the numerous comments on the assistants' certificates, I should like to know how many of the employers would pass an examination by experts in artistic photography.

In my own sixteen years' experience with about nine or ten employers, I have only been with two that would be called photographers, if photography examinations had to be passed previous to starting business.

I am not speaking of the backyard type, but of the class that mainly employ general assistants or men that can do everything. My present employer pays me 50s. weekly to manage his business, and he has not the remotest idea how the work is produced. If I left he would simply get another managing operator, but is he competent to give me a reference on which to base a certificate? I think not. My case is not isolated, as many assistants can testify.

Hoping you have space for my ramble, I remain, yours, etc.,

A SUBSCRIBER.

#### THE INVENTION OF THE CARBON PROCESS.

##### To the Editors.

Gentlemen,—In reference to your statement that "carbon printing, as everybody knows, was invented by Mr. J. W. Swan, and published by him in 1864," a practical carbon process was invented by Mr. Swan, by his use of collodion as a coating to hold the exposed film together; but Mr. Edwards invented the carbon process, in which the slight soaking of the film proved effectual in holding it on the developing sheet. At that time Mr. Blair, and many others (myself for one), were trying to get rid of the grain caused by the use of paper as a support; and Mr. Swan obtained that end by the use of collodion. That was all, for his process was not worked on a commercial scale. At least, when Mr. Skelton came to Scarborough he used the Edwards process.—Yours, etc.

J. D. COOPER.

36, Clarence Street, Kingston-on-Thames,

[Our correspondent is quite under a misapprehension. Mr. Swan (now Sir J. W. Swan) did invent the carbon process as practically worked to-day. He made the tissue on paper as well as on a collodion film, developed the print on a temporary support, from which

it was afterwards transferred to a permanent one. This process he patented (No. 5031864). Mr. Ernest Edwards did not invent the carbon process. What he did was the invention of a transfer paper coated with gelatine, rendered wholly, or partially, insoluble with chrome alum as a permanent support. This invention he patented in 1868 (No. 2201). This is the paper now in general use. Mr. Swan was working the carbon process (commercially) soon after his patent was secured. We may mention that the presentation print (15 x 11) for 1866, of the old South London Photographic Society, was printed in carbon by Messrs. Mawson and Swan at Newcastle. The prints were made on tissue, as used to-day, and developed on a temporary support, and afterwards transferred to a permanent one.]

#### AN APPEAL FOR HELP.

##### To the Editors.

Gentlemen,—May I beg the favour of a small space in the columns of your valuable paper to make an appeal to all my fellow-workers and readers of your journal on behalf of Mrs. Sargent, a widow lady, and an old worker in the profession, who is in very sore need.

In the "Too late for classification" columns of the B.J.P. issue for April 13 will be found an advertisement very kindly inserted by our esteemed friend, Mr. Snowden Ward, on her behalf, and my object in writing is to call the attention of your readers—both trade workers and professionals—particularly to this, and ask them to bear it in mind, so that if any of them may be called upon by this poor lady they may feel ready to render any little assistance they may be able, however small.

From my conversation with her a few days back I feel confident that hers is one of those cases deserving our attention. Do not let us, therefore, conflict hers with others, only too sadly numerous which do not. Some may say times are bad. They are; but not so bad as they are with her, and to those who argue that they have no concern in such matters and are free from any responsibility, I would respectfully refer them to the second clause of Mr. Pirie MacDonald's masterly article on photographic ethics appearing in your issue of June 22, "Our duty to each other."

Hoping, for the sake of suffering humanity, that some will recognise their duty, and believing that, when opportunity offers, there are many who will not be slow to do it.—I am, yours very truly,

J. HAMILTON CHRISTIAN.

48, Park Road, Peterborough.

#### A NOTE ON THE SENSITOMETRY OF PLATES.

##### To the Editors.

Gentlemen,—I am obliged to Mr. Sheppard for his courteous and interesting letter of July 6, but regret that I still fail to appreciate the value of his factors when they are used in the comparison of the qualities of various brands of plates. For if "the constant  $k$ , does not measure the rapidity of development for different plates," then I will be glad to know in what manner this constant is of use to the plate manufacturer, or user, and why it is quoted as a property possessed by a plate, if it is of no practical value.

It is stated that the constant,  $k$ , must be read in connection with the value  $\gamma\infty$ , but, as I pointed out in my letter of June 15, since  $\gamma\infty$  is calculated from  $k$ , it necessarily follows that if  $k$  is wrong, which it evidently is when using the tables and formulae published in the P.J., Vol. XLIV., p. 282, that the value,  $\gamma\infty$  must also be wrong, and I fail to see how the error may be corrected by using two fallacies.

Emphasis is laid by Mr. Sheppard upon the rather uncertain process of obtaining the values  $t_{\gamma,s}$  and  $t_{\gamma,1,s}$  by the graphic method. I admitted that it had its faults, but in my experience it is the method which gives the most practical and useful results.—Yours truly,

ARTHUR PATNE.

#### PROPOSED SOCIETY OF COLOUR PHOTOGRAPHERS.

##### To the Editors.

Gentlemen,—I think most people are aware that colour-photography has passed its experimental stage, and during the coming summer we shall undoubtedly see a great advancement in the quality of the

ults achieved by many ardent workers in this fascinating development of our art-science. But most of us are working in isolation, scarcely known to each other even by name, and many of us feel that time has arrived when some means should be afforded by which we may have the opportunity of comparing notes one with the other, of seeing and appreciating contemporary work.

It is therefore proposed that a society shall be formed having for its object the advancement of colour-photography, and the development of a fraternal feeling among its workers.

Among other suggestions it is proposed that workers shall be divided into two sections, and portfolios of work circulated in each, on the well-known postal club system. In the section for less skilled workers, helpful criticism and suggestions will be given by advanced workers in various processes; so that all classes of members should necessarily benefit by this and other means of intercourse and cooperation. I propose to call a meeting of members in London as soon as convenient, when the *modus operandi* of the society will be discussed, a committee appointed, and a code of rules submitted for their consideration.

In the meantime I shall be glad if ladies and gentlemen wishing to become members will send me their names and addresses.

I must, however, point out that we can only consider for membership those who have achieved some moderate success in the working of colour-photography in one form or another, and who are willing to submit specimens of their work if required, prior to acceptance as members.—Thanking you in anticipation, I am, yours faithfully,

HENRY J. COMLEY,  
Secretary pro tem.

Curry House, Stroud, Glos.

## THE TRUE CAUSE OF THE FORMATION OF THE LATENT IMAGE.

To the Editors.

Gentlemen,—Please accept my thanks for the notice you gave my article in your magazine of June 8th.

I also permit me to call your attention to some points which in the course of my business you overlooked.

In p. 5, paragraph 6, you will find that I created the latent image by magnetism. An experiment so simple that any one can repeat it, and assure themselves of its correctness.

Placing a sensitised photographic plate before the end of a simple electro-magnet (a spark-coil composed of a laminated iron core surrounded with five layers of cotton-covered copper wire, connected to five dry-cells, whose current was broken about sixty times a minute), the pulses of magnetism radiated from the pole adjacent to the plate, passed through the paste-board box and black paper wrapped around the plate, and made the image shown on the first page of my work.

Proving:—First, that the "latent image" is caused by ozone, which is the product of oxygen plus magnetism, and whose real use was thus shown for the first time;

Second, that the X-rays are a longitudinal propagation of magnetism, since I was able to produce a genuine X-ray picture of the Crookes' wheels shown, without the aid of the celebrated Crookes' tube. I have since built an X-ray apparatus embodying this principle, which will do all that the Crookes' tube accomplishes.

Third, since we can create the ozone image with the Crookes' tube, and electricity, it proves that electricity is the same force, and that electricity is not "ether waves" but magnetic waves. That an electron or "corpuscle" is but a charge of magnetism.

That so few experiments were given in the work sent you was due to the fact that my time for the lecture was limited to less than an hour, and so the details of but one experiment for each fact presented could be given.

I leave this matter with you for the present, as I am at work on a manuscript for a second edition of "The Primordial Energy," and will be soon able to send you a copy, in which many more experiments will be given in proof of the position I have taken.

Trusting that you will give this explanation of my work a place before the readers of your valued magazine.—I am, sincerely yours,  
BENJ. W. SANDS.

Springfield, Mo., U.S.A.

June 25, 1906.

## Answers to Correspondents.

\*.\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\*.\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*.\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\*.\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Isaac Perloff, 186, Commercial Road, London, E. Photograph of the Mayor of Stepney, Alderman Rowland Hirst, J.P.

F. de la Coze, Easebourne Road, Easebourne, Midhurst, Sussex. Photograph of the King and Queen at Midhurst on their way to open the King Edward VII. Sanatorium.

W. D. Brown & Co., West Bay Studio, Helensburgh, N.B. Photograph of the Rev. J. Baird.

POWDER COLOUR.—I should be most glad if you can tell me where to get the brown powder used for rubbing in backgrounds in standard brown carbons. I cannot get it at any of the dealers I have tried.—E. B. B.

The Autotype Company supply water colours to match their tissues, but whether they also supply powder colours we do not know. All good artists' colourmen supply powder colours, and we recommend you to get some and mix them to the tint you require. The pigments used in what is called "standard brown" tissue, we are told, are a crimson lake, indigo, and black.

POTTASCHE.—Could you kindly inform me whether "Pottasche" (I believe this is German) is, in English, potassium or potash (potassium hydroxide)?—E. L. LAUSTE.

Pottasche is the colloquial German term for potassium carbonate  $K_2CO_3$ .

RETOUCHING.—(1) I have been told that there was an electric retouching pencil some time ago in the market, which, when guided over part of negative to be retouched, would work in a stippling way, only very fast, and so save much time in retouching. Would you kindly inform me where such a pencil can be obtained? (2) Can you also tell me if there is a weekly or monthly paper published on studio work (operating and lighting)? A paper, I mean, which would be helpful to a young operator—one rather inexperienced.—ANXIOUS.

We have not heard of the pencil of late, but probably you would be able to hear of it from Marion and Co., 22, Soho Square, or Houghton, Ltd., 89, High Holborn. (2) There is no journal entirely devoted to studio work.

A READER FROM THE FIRST.—Matthews and Co., Gough Street, Gray's Inn Road, W.C., would probably buy the lot from you, and allow you for glass and silver.

RETOUCHING.—Your retouching is of very poor quality, but what can you expect after only working at it for such a period as stated in your letter. Your work presents no solidity, gradation, or modelling, and the necessary texture is entirely absent. The best advice we can give you is for you to at once place yourself

in the hands of an expert teacher, and have proper lessons, either personal or postal, instead of trying to teach yourself—always an unwise and hopeless task.

**SITE FOR STUDIO.**—I shall be greatly obliged if you will kindly assist me, through the pages of your valuable journal, with the following studio query, viz.—I contemplate building a small studio on a space of ground at the gable end of my house, which is facing due west. Size of plot I can build on is about six or seven yards square, and I want a show window and door to open on the highway. I should be glad of your advice as to best way of building same to obtain best light. The east is blocked by my house gable, also the north side by big overhanging trees across the road opposite, thus leaving only the south and west light clear.

If the road is wide and the trees not very high, you might build the studio so as to utilise the north light. But if the opposite conditions prevail, the best way will be to build so as to have the west light. In this case we should advise that the studio be erected on the "lean-to" principle, utilising the end of the house for one side; that would economise the cost of construction.

**COPYRIGHT.**—Is it necessary to place either the word "copyright," or the registered number on a registered photograph. A local lawyer says there must be either number or "copyright" on. I understood previously it was not necessary that there need be anything whatever to indicate a photograph being copyright. I have several postcards on the market which are registered and not marked in any way.—**REGISTRATION.**

There is not the slightest necessity to place the word copyright or the registered number on a copyrighted photograph.

**RETOUCHING (Dio. X.).**—Your one specimen of retouching sent shows, from a merely mechanical stipple point of view—as far as touch is concerned—a very excellent and clean effect; but this is not the highest attainment in the art, and something aiming at greater feeling, delicacy, and general respect for the likeness and texture suitable for a man's head of this size should be your object. In a few words, you are too laboured, and sacrifice much to mere stipple. Broaden your touch for such a face, respect the marked and natural hollowiness under the cheek bones, and see that your gradation from the cheek into line from nostril to mouth is a gradation in tone, and that it does not leave off too suddenly, so that this clearly marked feature is not reduced in force to the weak and broadened mark you have left. The forehead has lost in shape, the whole working is too youthful and pretty, and the character, if treated in a bolder manner, would have been more in keeping with the subject. Your friends and the majority of ordinary retouchers would consider this face beautifully worked; but you would not send to us unless you thought there was something lacking, and that something we have endeavoured to point out for your benefit. We have pleasure in answering you fully, for your work is otherwise so good, that if you can only disintegrate yourself from the fetish of stipple, stipple all the way, you will become a very fine retoucher.

**ENLARGING.**—1. I have half-plates I want to enlarge to 12 x 10 or 1-1 plate. I have not an enlarging camera, so I have knocked a box together and put negative at one end and focus by ordinary 1-1 plate or 12 x 10 camera with long extension, covering up with black cloth between box and lens. I have not enlarged before, only from print. Will you please say how I should proceed after I have enlarged from negative to 1-1 plate negative? Should I develop transparency deep? I did so, but could not get good negative from the transparency. Will ordinary plates be best, and should camera be well tilted up to good light, and how long exposure should be given? 2. Can you recommend any book on enlarging as above method? 3. Please give formula for stripping film from negative to enlarge film?—A. K.

1. A medium rapidity plate should be used and a full exposure given, and soft working developer, such as metol or adurol, and the transparency kept thin. The camera may be tilted up or not, just as is found the most convenient; the only point to observe is that even illumination is obtained. It is impossible

to give any idea of the exposure, as this will depend entirely upon the strength of light and other factors which we can possibly know. It is preferable to make a transparency by contact from the negative, and then enlarge this. 2. "Photographic Enlargements," by Geo. Wheeler, price 1s., or "Practical Enlarging," by John A. Hodges, price 1s., should answer your purpose. 3. The old formula for enlarging by stripping to immerse the negative in water till soft, then soak in

Hydrofluoric acid .....	1 oz.
Citric acid .....	1 oz.
Glycerine .....	1 oz.
Acetic acid (not glacial) .....	4 oz.
Water .....	32 oz.

till the film lifts at the edges, then coax off and wash two or three changes of water, and transfer to glass. hydrofluoric acid is not pleasant stuff to handle or stock, it is preferable to soak the negative in

Potassium fluoride .....	15 grs.
Water .....	1 oz.
and then transfer to	
Citric acid .....	15 grs.
Water .....	1 oz.

till it lifts. Or it may be soaked in a 20 per cent. solution carbonate of soda for fifteen minutes, and then transferred without washing into

Hydrochloric acid .....	50 minims.
Glycerine .....	1 oz.
Water .....	10 oz.

and then wash and transfer to new glass. The longer the negative is washed the greater the enlargement.

**CHROMO.**—We are not quite clear whether you want to learn the photo-mechanical side or the ordinary processes. Send us card and we will answer you.

**PHOTOGRAPHIC ETHICS.**—If I take a snapshot of a person in the street without his knowing that I have done so, can I, without his permission, publish them as a postcard for sale? Can I stop the sale of them? Does not the copyright belong to me? The person knows nothing whatever about it until he sees prints for sale.—**OLD GRUFFO.**

Unless the snapshot is a libel on the person he has no means of stopping it, and the copyright belongs to you. It is an open question whether it is wise to publish such a thing without the person's permission.

**S. ALTON.**—The alum was the cause of your trouble; this would decompose the hypo, giving rise to sulphurous acid and other sulphur compounds which would gradually attack the silver giving the characteristic yellow stain you obtained. The strength of the formaline is not of much moment, about 1 to 10 will do.

**LENS.**—1. Look through the advertisements of the almanac or the issue of the journal, and make a numbered list, and then we can help you. 2. You cannot have one with a lens which can be used for all plates up to 12 by 10, because for smaller size plates would naturally become a medium or narrow angle, according to the size of the plate. For the largest size an 8-inch should answer well.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

## SUMMARY.

The Key to the Convention Group is issued with this number as a double-page inset. A reproduction of the group, with notes on the card system of obtaining a key, is also given. (P. 572.)

The account of the Convention proceedings on and after Wednesday mid-day, with the papers read, is continued this week. Full reports of Colonel Grant's paper on "The Ordnance Survey Work" and Mr. Clayden's paper on "Cloud Photography." (P. 567.)

Mr. A. C. Braham gives us some useful hints for printing in tri-colour carbon tissues, a subject which at the present time is attracting a great deal of attention. (P. 566.)

Photography as an art craft forms the subject of our leader this week. The article is a plea for the recognition of photography as an art by itself, and not as a means of servile imitation of other graphic arts. (P. 564.)

"The Action of Alums and Aluminium Salts on Gelatine," the translation of a paper by MM. Lumière, which contains some useful practical information. (P. 573.)

A brief note as to the Printing and Allied Trades Exhibition, now open at the Agricultural Hall. (P. 574.)

We would draw the attention of our readers to the fact that the exhibition of flower photography and animal studies by Mr. Henry Levens at our offices, which has been a great attraction, closes to-morrow, July 21.

## EX CATHEDRA.

### The Convention in 1907 and After.

By the selection of Hereford as the place of meeting for 1907 the Convention is accepting the invitation of the Herefordshire Photographic Society, with whose offer of hospitality is joined a hearty assurance of hospitality from the municipality. In electing to the Presidency Mr. Alfred Watkins, of Hereford, the Council has not merely done the inevitable thing in view of its 1907 venue. It has recognised Mr. Watkins's position in the photographic world as that of one whose name is a household word, and whose writings entitle him to be looked upon as the holder of views formed only after a long series of experiments.

### Convention Meeting Places.

By the adoption of a rule proposed by Mr. E. J. Wall and afterwards modified, on the proposition of Mr. C. H. Bothamley, the Convention finally enunciated the policy that whilst it welcomes invitations from towns where its meetings may be held, it may take the initiative in choosing a place, and that by adopting this course it may hold its meetings at places which are highly desirable from its point of view, and yet cannot be expected to invite the Convention. The discussion which followed the proposition showed that the members were content to leave the matter in the hands of the Council, and the publication of their policy and motives should be to the advantage of the Convention for the future.

**Photography a Fine Art.** The Austrian Reichsrat, which may be compared to our House of Commons, has definitely decided that photography is not a mechanical process, but a fine art. This decision, whilst it may at first sight seem somewhat ludicrous, is of considerable interest to professional photography in Austria, because it frees it from certain stringent laws as regards apprenticeship, etc. This decision will not, of course, affect the opinion of those men like Mr. Joseph Pennell and others, who consider photography but a base and degraded mechanical art; nor will it improve the pictorial quality of the average work, though it may hereafter be quoted as a still further proof, by some writers, that the contentions which they have always somewhat blatantly upheld are correct, and have now received the stamp of the Reichsrat.

### The Muddle of the Spectroscope.

At a recent meeting of the R.P.S. a well-known spectroscopic worker was called to order for showing the spectrum with the red end to the left and not at the right, as has been recently decided by some of the leading scientific societies.

This is somewhat confusing at first, as we have all of us been for so many years in the habit of doing just the reverse, which really seems the most reasonable method after all, for we are still in the habit of talking of the A, B, C, D, and E lines, and it comes but natural that these should run as one reads. Even if we throw over this system and adopt the more universal scientific method of talking of  $H\alpha$ ,  $H\beta$  and  $\gamma$ , we still have the anomaly that these read from left to right, and it is quite possible that  $Na_1$ ,  $Na_2$ , will not be recognised as the familiar  $D_1$  and  $D_2$ . Then again  $D_3$ , the well-known Helium line, wants renaming, and the familiar HK lines in the ultra-violet must be called Ca. Supposing we accept the whole of these revisions, we are then met with the difficulty that the complexity of spectra of such simple elements as calcium is so great that one would have to continuously refer to an index of spectra to know what line was meant. One might also argue that the now accepted method is wrong on the ground that the wave lengths first visible are the extreme red, and as the colours brighten so the wave lengths shorten; therefore the logical way would be to record them, as we now read, from right to left.

\* \* \*

**Dissolving Hydroquinone.** A writer in the "St. Louis and Canadian Photographer" states that if any difficulty is met with in dissolving hydroquinone, or if it crystallises out of solution in cold weather, the remedy is to add a little "wood alcohol" and shake well. The term "wood alcohol" is somewhat vague, and may mean either methyl alcohol or wood naphtha, which latter is sometimes called wood spirit. Neither of these additions prove satisfactory in our hands. Both tend to produce a discoloured, cloudy solution with an unpleasant smell, and the solvent effect of methyl alcohol does not seem to be very great, though the wood naphtha is more effective. On the other hand, ordinary absolute alcohol rapidly dissolves the hydroquinone, and gives a clear solution. Very little is required, but absolute alcohol is expensive, and we do not see why it should be resorted to when plain water is just as effective. Concentrated solutions crystallise out readily when the temperature falls, but if the hydroquinone does not exceed eight grains per ounce of hydroquinone stock solution we find no trouble in keeping the solution through cold weather. Solution in the first instance is greatly assisted by using hot water, and possibly a solution so made is less likely to crystallise out than one made in cold water. It is, however, unwise to use boiling water, as this tends to produce colouration. The best method is to add the hydroquinone to a cold solution of the preservative, and then add hot water in small quantities, and shake well between each addition. When all is dissolved cold water can be added to make the required total bulk of solution. By this method solution is complete in a few minutes, while something like twenty-four hours is required if cold water alone is used.

\* \* \*

#### Loss of Brilliance in Negatives.

There is a tendency for negatives made in the hot weather to lack brilliancy, the shadows being veiled though full of detail. Where this occurs there are several points to look to, any one of which may be causing the trouble. The increased strength of the light may be to some extent unallowed for in exposing, with the result that the plates are over-timed. The temperature of the developing solutions rises above the normal, and as a consequence these solutions are more active. They should, if possible, be cooled either by setting the bottles, or if concentrated stock solutions are used, a jug of water

for mixing the developer, in a mixture of crushed ice and salt. Failing ice a pound of crystals of ammonium nitrate may be added to a pint of water placed in a porcelain or wooden tank, and on solution the temperature will be found to fall many degrees. The developer may be set in this nitrate of ammonia solution to develop in the hot weather and to diminish slightly the amount of alkali, though in modifying the formula should be taken to avoid any prolongation of development which might start frilling, or at all events, a generous softening of the gelatine. The dark-room window may be looked to, for if of ruby fabric the bright light of spring and early summer may have bleached it sufficiently to render it inefficient. Another cause of slight fogging is to be found in the condition of the interior of the camera. If the blackness of the surfaces become impaired, or even if a film of lightish dust settles, sufficient light may be reflected to produce distinct veiling of the shadows of the negatives. Further, a camera left in a hot, dry, studio, particularly if it be a piece of new apparatus, may warp somewhat, or glue attaching the bellows dry excessively and come away with the result that slight leakage of light occurs. The camera should be carefully examined with a view to this and any suspicious points attended to.

\* \* \*

#### Specimens of Orthochromatic Work.

We have frequently advocated the use of orthochromatic plates with light filters for certain classes of work, such as the photography of inland furniture, while for picture copying and a large proportion of landscape and local view work their use has been obvious for many years. Even amongst the ranks of amateur photographers there are thousands who not only do not understand the principles underlying orthochromatic photography, but who do not quite appreciate the gain of a colour-corrected photograph. If this be so amongst those who are users of dry plate or film it will readily be seen that the general public understand still less. It would, we think, be worth the professional worker's while to make a few specimens showing the great advantages accruing from the use of the colour-sensitive plate and to have these displayed in the reception room. A water colour or chromo-lithograph of about eight inches by six might be photographed the same size on an ordinary plate as on an isochromatic plate with a suitable screen, and the original and both reproductions could be framed together. Two or three vases of yellow, orange and blue could be photographed in the same way on both kinds of plate, even a test colour chart could be employed. The original should be selected with a view to the production of striking examples. The advantage of such specimens would be two-fold. They would attract attention and improve one's clients with the fact that the worker understood the higher branches of his profession, and they would in many cases lead to additional work by suggesting visitors to one's establishment the photographing of paintings or objects of art. The preparation of the specimens should not occupy more than a few hours if undertaken systematically, and we should suggest the use of a yellow-green sensitive plate with adjusted filter, increasing exposure about thirty times, unless the worker is accustomed to handling red sensitive ortho-plates.

\* \* \*

#### Portable Light Filters.

Much has been heard from time to time of the necessity of employing specially worked glass for the construction of light filters to

sed with the modern highly corrected lens. The last year or so several of the firms making orthochromatic plates have issued light filters consisting of the stained gelatine or collodion film without any supporting or protecting glass, and such stained films have been supplied with the idea of affording the means of making experimental exposures. We were discussing the matter with a landscape worker the other day, and he admitted that until quite recently he had carried two or three comparatively thick cemented filters about three inches square, but that he now used the stained film mounted on a card, which was clipped to the front of the roller blind shutter held inside the camera. The saving in bulk and weight was a consideration when doing a long day's tramp, and so far he had found no falling off in definition, even when using such apertures as  $f/8$ . We do not see why the film idea should not be taken a step further and films issued mounted on a slip of black cardboard at the cost of a few pence. The filter could then be slipped behind the lens, which is undoubtedly the best position for it, just as received and without the necessity of any trouble in attaching to card. A convenient method of holding the card behind the lens is to cut two small V shaped notches or snips in the opposite ends and to screw into the woodwork two little round headed screws. The card may then be sprung into position and will hold quite firmly yet may be removed in a moment.

\* \* \*

#### Halation in Portrait Negatives.

With the more brilliant lighting usually obtained during the summer season the risk of halation is considerably increased, and the careful portrait worker takes

steps to avoid what is a serious blemish to a good photograph. To back plates when loading them into the slides of a studio camera is so simple a matter that there is no excuse for its not being done in every instance. If the plates are to be developed immediately after exposure it is well to use a slow-drying backing preparation which may be readily removed with a damp sponge as soon as the slide is returned to the dark-room. Where development is left until the end of the day the backing should be, at any rate, nearly dry before the plates are placed in the storage boxes. They will, of course, be placed film to film. It would probably be better to employ ready-backed plates in order to obviate the risk of the backing causing the plates to stick together if not quite dry, and the extra cost is so slight that it is certainly worth while to the "one man" studio-worker in the saving of time. Another point, if the avoidance of halation is sought, is to use an orthochromatic plate. We believe one of our best architectural workers employs them with very satisfactory results for this reason, and only a day or two ago we saw a little interior of an ordinary room taken on such a plate in which two windows were included, the sash-bars and even the details of the muslin curtains being perfectly clear and free from halation. The plate had not been backed, though the result would in many cases be improved if this were done. We are, of course, referring to the use of the orthochromatic plate without a light-filter, for, as is known, halation is more pronounced when using the filter, owing to the diminished latitude, the plate possessing less opacity to the light forming the image. The orthochromatic plate exposed through a light-filter should invariably be backed, preferably with black backing.

\* \* \*

#### Wanted!

The wants of the photographer are numerous, and under this heading we might mention improved specimens of nearly every article that he uses. But the particular want that we have in mind is a com-

paratively humble one, and possibly many photographers do not realise that it is a want. They think that they have it already, and do not realise the ill effects of its absence, which effects are subtle and difficult to detect, though very deleterious. The thing may appear simple, but it is not so in fact, for many brains have puzzled themselves vainly in attempts to supply the want, which is that of a good dead black. Dead black, so-called, "varnishes" are numerous, but none of them are really "dead black," or as efficient as is desirable. Chemical methods of blackening metals are equally unsatisfactory, and, whether chemical methods, varnishes, or stains are used, the method that gives the nearest approach to a dead surface also gives one that either flakes off or becomes glazed on very slight friction. A glance inside a camera will always reveal a quantity of white light reflected from a number of so-called dead black surfaces. The lens mount, the woodwork, and the cloth-lined bellows all contribute their share, and there is no doubt whatever that the image on the plate is materially degraded or "fogged" by this reflected light. It does not appear that this should be one of the problems that can never be solved, but we doubt if it will be solved until lampblack is definitely abandoned as the pigment and is replaced by some other substance that will not polish on rubbing. It appears to us that the solution of the problem depends on this, but we have not found any suitable substance, and cannot make any suggestion beyond one that the need of a good dead black is an urgent one. The inefficiency of the ordinary varieties of dead black varnish is proved by the fact that we habitually use one as a black polish. One or two coats of the varnish and a slight rub with a cloth gives almost exactly the effect of polished ebony.

\* \* \*

#### Keeping the Studio Cool.

Up to the time of writing we have had warm weather but no great heat. It is little use, however, suggesting methods which may reach our readers too late, and precautionary measures must be suggested beforehand. In the first place, those studios in which the sun strikes the glass are almost always the hottest. If, therefore, some form of blind can be erected which will prevent this, an important step has been taken. With a ridge-roof studio glazed on one side only, and that the north, it is a simple matter to run a screen of light boarding attached to a firm framework so that even at midday the sun's rays will not reach the glass, while the light needed for photographic work will be quite uninterfered with. Where the worker is unfortunate enough to have his glass towards the south, south-east, or south-west, it is obviously impossible to so screen the glass, but even then we think a white calico blind, or blinds, might be fitted outside the glass and about a foot away from it, so that the direct rays of the sun were excluded, the intervening air space being heated rather than the air inside the studio. The white calico would also reflect the heat to a great extent, and if it obscured the light too much for rapid exposures it might be drawn up on its roller while sittings were being made. The white painting of wooden studios aids materially in keeping them cool, and it is often worth while painting a slated roof, particularly if the inside ceiling or match-boarding is near to the slates, the air space being slight. Very efficient ventilation must, of course, be arranged, the outlet being as near the ridge as possible, while the inlet should be near the floor. Ice is so readily obtainable, and at such a low price, that in very hot weather its aid in rendering the studio comfortable may always be secured. A block of ice, especially if arranged in a little fernery with a tiny fountain, always makes the studio look delightfully cool.

## PHOTOGRAPHY AS AN ART CRAFT.

MR. HORACE MUMMERY in his lecture on "The Picturesque in Landscape" dealt severely with attempts to produce by photography results that bear a resemblance to those produced by other graphic methods, such as crayon sketches, etc. His point of view was, of course, that taken by all artists, but, unfortunately, it is not the point of view taken by all photographers, many of whom evidently have yet to learn that such resemblances are artistic crimes if produced intentionally, and misfortunes if they occur accidentally.

The methods of every genuine artist are governed by his materials, not as a matter of compulsion, but intentionally, because long experience has shown that no good results can be produced otherwise. This law is well understood by every painter, sculptor, architect, or designer or craftsman of repute in the big world of art, and, in that world, it is ignored only by the cash-at-any-price individual, who lives on "pot-boiling" and "taking in washing," and by "ghosts." Why then should it be ignored as much as it is by photographers? The usual argument, or rather excuse, seems to be, "We don't imitate painter's methods, intentionally, but if a photograph happens to resemble a chalk or a water-colour drawing or sketch, what harm is there in it? If a chalk drawing is pleasing and a photograph that happens to look like a chalk drawing is also pleasing, one should be respected as much as the other." Arguments of this sort only serve to show the want of general art training among photographers, to which want we referred some time ago in an "Ex Cathedra" note on Mr. J. C. Dollman's lecture at the Society of Arts. The answer is simple enough to anyone who has been through that training; and it is this: The only kind of photograph that can be called a work of art must exemplify the beauties of photography which are peculiar to photography. A result that resembles a chalk drawing shows evident want of consideration of these special beauties, and never by any chance does or can resemble anything but a very bad chalk drawing. The contention that imitations are not made cannot be supported, for we have seen many of them.

At various times and various exhibitions we have seen imitations of red chalk sketches, and of charcoal sketches on brown paper. We have seen imitations of engravings and of pencil drawings, and even imitations of pencil line work that must have required a deal of misdirected energy to produce. These things had none of the quality of photographs, while, if they were to be judged as chalk, charcoal, or pencil sketches, only one verdict could be possible, and that would be "bad." Any art student could easily reproduce these efforts in the actual materials that they resembled, but we should feel sorry for him if he were to be so rash as to submit the results as examples of his own work to his master. The value of any artistic method or material depends on those particular qualities in which it differs from others. It is possible to make water-colour drawings and oil paintings that closely resemble one another, but there is no art in so doing, for both results are essentially defective. The one does not show the beauty peculiar to water-colour, nor the other that peculiar to oils. The same thing applies to photographs. The more a photograph resembles the result of a different method the less meritorious is it as a photograph and the less is its artistic value. It is sometimes argued that if a

man cannot use crayons he is justified in getting as near to a crayon result as he can with the aid of photography. But a water-colour painter who cannot use oils and the fore tries to imitate them in his own media, does nothing more than waste time and lose reputation, and the same thing applies to photographers, though, up to the present too many fail to appreciate the fact.

This brings us to the consideration of what are the peculiar beauties of photography that must be exemplified in a photograph that claims to be a work of art. The first is undoubtedly delicacy. Delicacy of drawing, delicacy of detail, delicacy of gradation in light, shade, and shadow. All which *can* be attained in the craft of photography in a manner that cannot be rivalled in any other craft, and all which are often condemned, either separately or *en bloc*, by the untrained artist on the very ground that nothing like these qualities is to be found in the work of other craftsmen. Possibly he imagines that the water-colour painter neglects these particular qualities for choice, but if he will spend, say ten years, in the study and practice of water-colour painting he will find that anything approaching the peculiar delicacy that is possible in a photograph is unattainable with brush and colour. He will learn enough to regret this impossibility, while at the same time he will learn how skill can render the limitations of a craft of small consequence by utilising to the utmost its possibilities. The want of the photographic type of delicacy in a fine water-colour drawing is rendered of no account by bringing out in full force all the beauties peculiar to water-colour and impossible in photography.

The second great quality of photography is the truth attainable. The true delineation of the form of the object in front of the camera is of value and so also the true representation of gradation, which involves the true representation of distance and of perspective. Nothing but practical training will probably convince the average photographer that these things are of any value, and even that training may fail. When acquainted with the hopeless inadequacy of brush, pen, and pencil for purposes of absolutely true delineation he is apt to think that what we may term truth of sentiment (which is the artist's compensation for want of true delineation, and is, in fact, one of his most valuable assets) is the thing to be aimed at in photography, while the other form of truth can be safely neglected. As a matter of fact, this quality we have termed truth of sentiment is more of a subjective than an objective fact. The precise nature of the sentiment differs with the observer, and, while the painter can paint his own impression of the sentiment (which is the truest and highest form of "Impressionism"), the photographer can only represent what is in front of his camera, and if he neglects to represent that truly, he neglects the greater part of the truth that his craft is capable of giving. As a rule he does not consider this kind of truth to be of any value. He thinks it is attained automatically, without his personal control; and, if he belongs to a certain cult, he considers the advertisement of his own valuable personality to be the touchstone of art in any work produced by himself. He is, however, wrong all through. The perfect delineation attainable in the camera is very rarely attained, and very seldom is it seen on the walls of an exhibition. Take for example the representation of distance, which is a most difficult problem to the painter, and such a comparatively easy one to the photographer. How seldom do we see a photographed distance, and often a faked smudge that is supposed to represent it?

The impossibility of absolutely perfect drawing is one of the limitations that guide the painter into the path where the greatest possibilities of his craft are available. The

possibility of representing anything that is not in front of the camera is, or should be, a limitation (*i.e.*, guiding boundary) leading the photographer to understand that he must make the utmost use of the unrivalled facilities of his craft in delicate and accurate rendering. If he neglects these he has practically nothing left of value, and the result will only serve to illustrate the well-known facts that the photographer is dependent on "taking things as they are," and that his craft, minus its most characteristic possibilities, is woefully inferior to that of the painter.

### ALBUMEN VERSUS GELATINE.

ACCORDING to some recent writers it seems to be an admitted fact that prints on albumen paper are more permanent than are those made on gelatine papers. Also that they possess better all-round qualities. The latter may at once be conceded—according to the majority of opinions. But the former may be open to question—or at least so far as the modern method of produced albumen pictures is concerned. It is an undisputed fact that there are hundreds of albumen prints in existence that were made in the fifties and early sixties that, up to the present, show no actual signs of deterioration so far as the image itself bears evidence. The whites in some instances may show some trace of yellowness, but the actual image is as strong and vigorous as ever. These facts are proof that albumen prints have been made that are, to all intents and purposes, permanent pictures. This is very strong evidence, and it is probable that it is on this fact that some writers assume that albumen prints are more stable than gelatine ones, seeing that so many of the latter show unmistakable proof, after a very short life, of material change.

Will, however, the albumen prints of the present day prove of the same stability as those of the earlier days of photography? We question it, as quite different conditions prevail now from those that existed some forty or more years ago, and it may be well to explain to modern workers what they are, although it is not the first time that the subject has been dealt with in these columns. It may be pointed out, at once, that prior to about 1860, all the albumen prints were, of course, made from collodion negatives, and they were toned and fixed in a combined bath, which was an exceedingly strong one and contained only hyposulphite of soda, chloride of gold, and water. The proportion of hyposulphite of soda was usually ten ounces to the pint of water. The toning of the prints was a slow operation, usually taking an hour or more and frequently much longer, so that there was no question then about their being completely fixed long before the desired tones were obtained. Frequently, however, the bath was used long after it was quite exhausted of its gold, as is often obtained by sulphur toning. Yet many of these sulphur-toned prints have withstood the test of time, and though the lights, in many cases, have become yellow, the images themselves are practically intact.

Let us now examine the conditions under which these old photographs were made. In the first place the paper was distinctly different from the albumen paper of to-day. It was but comparatively slightly albumenised, and the albumen was heavily salted—containing about double the

amount of chloride that is used at the present time. This paper was sensitised on very strong solutions of nitrate of silver—usually from eighty to a hundred grains to the ounce of water, and no organic acid whatever was added. Here we see at once some of the differences prevailing then and now. But this only a part and not, perhaps, the most important one. The negatives made up to the time just referred to were developed with pyrogallie acid and were made very dense, and often took a whole day to print. The kind of density then was, again, different from what is termed density in gelatine negatives. Although the high lights were so very strong, the shadows were clear glass, and, as a consequence, when printed, the shadows were strongly bronzed. The bronzing, however, disappeared in the strong toning and fixing bath. When the prints were taken from the printing frame the image usually showed strongly on the back of paper, thus proving that it was largely in the paper itself, and not confined, as at present, only to the albumen on its surface. It necessarily consisted of a large quantity of metallic silver, which required, as a matter of course, a considerable deposition of gold in order to obtain the rich purple tones then in vogue. Hence it will be realised that by reason of the large quantity of metal of which the image was composed it could better resist deleterious influences than would the extremely attenuated ones such as we get on modern lightly salted and lightly sensitised albumen paper when it is printed from weak negatives of the present day. If anyone will take the trouble to unmount one of the very early albumen prints, and examine it by transmitted light, he will at once see how exceedingly strong is the image, and how much it is in the paper as compared with a modern albumen picture.

In the early sixties iron generally superseded pyrogallie acid as a developer, but the negatives were still made very strong and dense. In fact, at that time density was one of the qualities looked for in a good negative. It was about this period that the alkaline method of toning became universally adopted, and the old toning and fixing bath abolished. Few old family albums there are that do not contain some *carte* portraits, taken about that time, that still show no sign of fading. At that time long washing was considered necessary in order to secure stability, and ten or twelve hours were often given. In some cases even the prints were left in water from the Saturday night until the Monday morning. This long washing was, of course, a fallacy which has long since been dispelled, and it obviously had some injurious action on the pictures, yet owing to their robust constitution, they withstood it. But we much doubt if albumen prints of the present day would do so without a considerable loss in tone and vigour.

Apart from the strongly salted and sensitised paper that used to be employed at the period to which we refer, it will be seen from what has just been said that the negatives, by reason of their great vigour, were an important factor in the case, as they caused so much metal—silver and gold—to be reduced in the printing and toning. Weak negatives were of no use with the old albumen paper.

The object of this article is to point out that the old albumen prints made forty or fifty years ago, good as many of them still are, cannot be taken as conclusive evidence, as some writers seem to have done, that present day albumen pictures, made on the modern highly albumenised and lightly-salted and sensitised paper, printed from comparatively feeble negatives, will prove so much superior, as regards permanency, to those made on gelatine ones—all things, as a matter of course, being equal in the care bestowed on their production.

## TRICHROME CARBON PRINTING.

PROBABLY no one cause militates against the adoption of trichrome carbon printing as much as the supposed difficulty of multiple double transfer. The idea of difficulty, however really springs from failure to recognise that the conditions that might cause trouble with the transfer of a print printed deeply in a single tissue (thus giving an image in comparatively high relief, with abrupt steps from light to deep shadows) do not apply to the lightly printed images forming trichrome carbon prints, as the deep shadows in the complete print consist of three thin images separately transferred.

Thin transparent celluloid, is I am convinced, the most convenient temporary support to employ; held upon a piece of opal during development it allows the depth of image to be correctly judged; there is, of course, no stretching and no absorption: a decided advantage in making a number of prints, as time is gained in drying between successive transfers.

### The Sensitising Formula.

Sensitising should preferably be done in a bath of fine recrystallised, or granulated bichromate, without the addition of ammonia as there is a slight tendency to frill with trichrome tissues; two minutes' immersion is desirable, as that time ensures complete diffusion of the sensitising solution through the tissue.

### Timing Exposures.

Approximately correct exposures will be in the ratio of two for the yellow image and one for the red and for the blue; as the needful exposures are very short the use of an actinometer for each exposure is not generally convenient, but a reliable method is to gauge the strength of the light by any actinometer with which one is familiar, that is to say, to measure the time taken to secure a standard tint and to give proportionate time exposures to the three images.

Absolute uniformity and correlation between the three exposures is not likely to be secured, but when a number of prints of slightly varying depths have been developed they can, by superimposing the images on the celluloid, be separated into threes which combine harmoniously together.

### The Temporary Support.

The celluloid temporary support must be waxed each time before use, using as little waxing solution as possible to form a film on the celluloid, which should be at least two inches larger in each dimension than the transfer paper it is intended to use. Support the celluloid on a piece of opal during development; this allows the hot water to be splashed on the celluloid without fear of buckling, and enables the progress of development to be readily judged. When the prints are considered to be correctly developed they should be put into cold water to stop the action, and may then be matched in threes by putting yellow, red and blue images on each other, judging their correctness, any image too deep being put back in the hot water for further development, or employed with other deep images to form a dark print.

### How to Transfer.

Tissue and transfer paper should both be cut in the same direction of the band, the expansion of paper being negligible in the direction of the length of the reel of paper, but appreciable in the width; the image on the celluloid will, of course, be larger than the negative by the degree of the expansion of the tissue; the transfer will, however, have expanded in the same degree, the register will be assured, expansion of the transfer being constant each time of wetting, provided the soaking is sufficient. The yellow image may be transferred without previous drying—the transfer paper, preferably a smooth single transfer, having previously been soaked in cold water for at least half an hour, and then in hot water 130-150 deg. Fah., till the coating of hardened gelatine feels soft and slimy. When this condition arrives, put the transfer back into cold water and then bring into contact with the yellow image on the celluloid and lightly squeegee.

The celluloid and paper should then be laid flat to dry, as hung up there is a risk of the paper, in shrinking during drying, buckling the celluloid and so splitting from the image. If, however, laid flat to dry, the paper in shrinking will cause the celluloid to curl to a slight but regular curve but will not buckle it. Allow to dry spontaneously in a warm room. The print when dry will generally strip itself without assistance.

When stripped it is necessary to remove the waxing compound adhering to the yellow image before applying the red image. This may be done by rubbing the surface with a rag wetted with a mixture of equal parts of benzole and turpentine, and then while still wet, rubbing with a little tripoli on a rag, polishing with a clean rag and the benzole-turpentine mixture. Allow to dry and then put in cold water with the red image on it; celluloid base, allow five minutes for expansion, then put both into a transfer solution made of 1 oz. Nelson's No. 1 cut gelatin to 60 ozs. water. This weak mixture will readily liquefy when warmed and remain fluid at 70 deg. Fahr., which temperature should not be exceeded. Bring the two images into contact avoiding air bells, withdraw from the solution, placing the paper downward on any rigid support; the celluloid image can then be gently shifted until in register, then held in position by one hand while the squeegee is applied lightly.

The adhering images must then be allowed to dry spontaneously as before. When stripped, the compound yellow-red print must be freed from the waxing compound, soaked in cold water with solution, adjusted and squeegeed as before, dried and stripped. If a glossy surface print is desired the print may be left as it is, otherwise it should be rubbed with the benzole-turpentine mixture, the tripoli not being needed as there is no longer any question of securing contact.

The celluloid before rewaxing should be washed in warm water to remove any trace of gelatine adhering from the transfer solution.

A. C. BRAHAM.

THE BRITISH JOURNAL OF PHOTOGRAPHY—the "Times" of the photographic world—says "A.A.O." has been stirring up photographers to impress themselves rather more upon the twentieth century. It thinks that some of them are a little mediæval. It has urged them to consider various ways of advertising their business. Certainly all of us must keep up with the procession if we want to hear the music. If the photographic art needs any helper, we certainly feel as ready to help as any barrister is ready to rush to the defence of injured innocence—for a consideration. Why should not photographers seriously set themselves to supplying photographs of all the topical events which lend themselves to such representation,

and which are suited for reproduction by the engraver. And send them to us to engrave. We put to them the "Hypo"-thesis that there is a good deal to be made in this way.

"A.A.O." with apologies to T. P. O'Connor, M.P., or "All About Ourselves," is the title of the last and first issue of a twelve-page journal, dated July, which has been published by Carl Hentschel, Ltd., which, like the other bright one-issue journals which have emanated from Fleet Street, is good printing, and bright and breezy in matter, though naturally being "all about ourselves," might draw on it the reproach of being egotistical, but in these days a little or lot of this pays.

# THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

## TWENTY-FIRST MEETING IN SOUTHAMPTON.

annual meeting was held in the Philharmonic Hall on Wednesday, president, Mr. E. J. Humphery, in the chair. As reported in our last, the invitation of the Hereford Photographic Society was accepted for 1907, and a letter was also read in the Mayor of Hereford cordially seconding the invitation to the society. The following were then elected on the council for the ensuing five months:—

G. B. Bainbridge, Morpeth.  
Harold Baker, Birmingham.  
Godfrey Bingley, Leeds.  
G. E. Brown, London.  
Henry Coates, Perth.  
C. C. Cook, Southampton.  
W. J. Croall, Edinburgh.  
T. R. Dallmeyer, London.  
W. E. Dunmore, London.  
Alfred Ellis, London.  
S. H. Fry, London.  
T. K. Grant, London.  
C. B. Keene, Derby.  
Sydney Keith, Hounslow.  
Furley Lewis, London.  
C. Phipps Lucas, London.  
F. J. Mortimer, London.  
A. F. Mowll, Liverpool.  
G. W. Norton, Oxford.  
Rev. T. Perkins, M.A.,  
Blandford.

Walter F. Potter, London.  
Ralph Robinson, Redhill.  
J. A. C. Ruthven, Dublin.  
F. G. Ryder, Southampton.  
P. R. Salmon, London.  
F. H. Sanderson, Cambridge.  
T. Scotton, Derby.  
A. Seaman, Chesterfield.  
H. M. Smith, London.  
W. H. Smith, Purley.  
Henry Spink, Brighton.  
W. Taylor, Leicester.  
G. T. Vivian, Southampton.  
J. H. Walker, Leeds.  
E. J. Wall, London.  
H. Snowden Ward, London.  
Maj.-Gen. J. Waterhouse,  
I.S.C., London.  
J. B. B. Wellington, Elstree.  
A. Werner, Dublin.  
S. H. Wratten, Croydon.

Mr. E. J. Wall, who was unable to be present, proposed that no invitation should be accepted for the 1906 meeting, and that a committee of five members be appointed to determine the town for that occasion, and to report to the Council. After considerable discussion and numerous amendments, it was unanimously adopted that: "Whilst the Convention will welcome invitations to hold annual meetings at particular places, they do not bind themselves to accept such invitations, and that it be the duty of the Council to report at each annual meeting as to the place or places which they consider suitable for the following meetings."

Mr. F. A. Bridge, the hon. sec., proposed a hearty vote of thanks to the local committee, and Mr. S. G. Kimber, for their arduous labours, which was duly acknowledged. A hearty vote of thanks was accorded to the hon. sec., and the members paid a visit to the Ordnance Survey Department, and thence to the group, the reproduction of which was given in our last, and the key to the same being issued with this number.

The annual dinner was held at the South-Western Hotel in the evening, the Mayor, Councillor H. Cawte, and Colonel Grant being amongst the visitors.

After the loyal toasts, Mr. C. H. Bothamley proposed "The Photographic Convention of the United Kingdom," which was responded

to by Mr. F. A. Bridge, who said that the future of the Convention was very largely in their own hands—a fact he did not want them to fail to realise. The way to ensure success was to take an even greater interest in its works and doings, and he wanted them to make the Convention a mirror through which could be seen the present and future of photography and photographers. He referred to the splendid welcome they had received at Southampton, and said they were all very much obliged to the local gentlemen who had worked to ensure comfort and success. Southampton possessed an excellent camera club, and the officers were hardworking men, who were doing their best for the advancement of photography. He had great pleasure in proposing "Success to the Southampton Camera Club."

Mr. Burrough Hill (President) was the first to respond on behalf of the local club, and he spoke of the great energy and enthusiasm which had been displayed by their secretary (Mr. Kimber), to whom much of the success of the club was due. He gave up a lot of time to the work of the club, and he deserved their best thanks. Mr. Hill referred to the natural beauties with which Southampton abounded.

Mr. Kimber (the local secretary) also responded, and said he considered it a very great honour to be allowed to reply in conjunction with the President. Mr. Burrough Hill had rendered the club splendid service, and they could not speak too highly of all he had done for them. The Southampton Club had been in existence for ten and a quarter years, and he thought he might say that during that time they had made themselves known in the photographic world. They esteemed it a great privilege to entertain the leading lights of the photographic world, and he was sure the club would benefit by the visit of the Convention. He acknowledged the many kindnesses which had been shown the club by many of the best photographers of the day, and he desired to take the opportunity of thanking Colonel Grant for having conducted them over the Ordnance Office that day.

Mr. Horsley Hinton proposed the toast of "The Visitors," and mentioned that they had representatives present from all parts of the world, including Australia, France, Belgium, and Holland.

The Mayor suitably responded to the toast, and expressed the hope that the Convention would enjoy increased success and prosperity now it had "come of age."

Mr. Rouse (Australia) and Mr. Ernotti also responded. Mr. G. Davison proposed "The Health of the President," which was enthusiastically drunk, and other toasts were "The Press" and "The Ladies."

On Thursday an excursion was made to the New Forest, Lyndhurst being the starting point, and, notwithstanding a brief but sharp thunderstorm, a most enjoyable day was spent.

In the evening a paper by Mr. A. W. Clayden was taken as read, and Mr. Horsley Hinton also spoke on "Combination Printing." Following these was a chat by Mr. F. Martin Duncan explanatory of his extremely fine series of cinematograph pictures of insect life, which, judging from the frequent rounds of applause and the large audience, was most thoroughly appreciated.

## METHODS AND HISTORY OF THE ORDNANCE SURVEY.

COLONEL GRANT delivered an interesting and highly instructive paper dealing with the methods employed at the Ordnance Survey Department. Although, he remarked, in introducing his subject, the programme stated his notes would be in reference to the processes of photography employed at the Ordnance Office for the reproduction of maps, he thought it might be interesting to them if, with the chairman's permission, he prefaced his remarks with a few notes on the history of the Ordnance Survey itself. In the short time at his disposal, it was impossible to give the history properly, and there would be a great deal he would have to leave out which might be of interest to some, but he could not under the circumstances help that. He was, he said, afraid that

survey and the reproduction of maps was a very serious subject, for he had been thinking all day whether there was not some humorous side to the question, and after going back over thirty years he could not think of one single joke in connection with it in all that time, and would be bound to treat the matter seriously. But with reference to survey and map reproduction, he could not do better than quote from a book, which was published thirty years ago, which stated that there was perhaps no great national work in this country which had hitherto been so little appreciated or understood as the Ordnance Survey. Certainly geographers and men of science, both at home and abroad, had learned to estimate it at its true worth, but, except in Ireland and Scotland, where it had made

more progress than in England, and where its uses and advantages were somewhat better known, the general public were by no means fully alive as yet to the great national value of accurate large-scale maps. Thirty years ago that was absolutely true, and it was true to-day. The objects to which national maps might be put were the following—the valuation of property for the equitable adjustment of taxation and assessment, the sale and transfer of land, railway and other civil engineering works, such as the construction of roads and canals, large sanitary and drainage schemes, military engineering works, hydrographical, geological, and mineral surveys, the reclamation and improvement of waste lands and of land from the sea, transactions affecting land as between landlord and tenant, statistical surveys, and the setting out and adjustment of parochial and other public boundaries. He mentioned them, he said, just to set them thinking and to help them to realise the usefulness of the work. After the Paris Exhibition of 1867, the French Government had a committee of officers to go into the whole question of the survey of foreign countries. They did so, and of the Ordnance Survey they said it was “a work without precedent and should be taken as a model by all civilised nations.” Speaking of the history of the Ordnance Survey he said it was now under the Board of Agriculture, previously it was under the Office of Works, before that under the War Office and under the Master General of Ordnance, from which it derived its name.

The first State survey that was made was probably after 1745 in Scotland, when it was found necessary, in order to follow the Scotch into the Highlands, to have a survey, and a map of one inch to the mile was made; this was not a trigonometrical survey. To get to the trigonometrical survey they must go on to the year 1784. It was then found desirable by astronomers to measure exactly the distance between the observatories, on the meridian, of London and Paris, and that was accomplished, the English doing the English side and the French doing the French side. The base line was measured on Hounslow Heath. This was finished in 1786, and then having got that triangulation the Government decided to go on and have a general survey. The new triangulation was begun from a base on Salisbury Plain, and so the survey progressed on a scale of one inch to the mile till 1824. In that year Ireland wanted a survey for the re-assessment of income tax, and it was decided to survey Ireland for that purpose, and as the small scale was considered inadequate, a scale of six inches to the mile was agreed to. Ireland was then surveyed at that scale, whilst England up to York had been only done at one inch to the mile. For once the sister island was satisfied that she had got the Government to do what she wanted, but he did not think she thought so long, for the income tax was raised by £50,000 a year. That survey in 1840 was finished, and the surveying parties came back to England, and the country having now got a six-inch survey saw the usefulness of it. Some people saw the advantage of a big survey, and twenty-five inches to the mile was the scale proposed and discussed generally, and between the years 1851 and 1860, Parliament could not make up its mind what to do. Then began that long controversy which has been well termed the “battle of the scales,” and which for eleven or twelve years seriously retarded the progress of the survey, and led to a large waste of public money. Between 1851 and 1862 no fewer than three select committees and one Royal Commission deliberated on the scale for the survey, and fourteen bluebooks were presented to Parliament. In 1851 the six-inch scale was stopped, and the one-inch reverted to; in 1852 the six-inch was ordered again. In 1853-4 the Director of the Survey was for fifteen months without orders for any scale at all. In 1854 the scale of one inch to the mile was partially adopted, and in 1856 Parliament sanctioned the prosecution of the work on this scale, whilst in the following year they refused the money for carrying it out. For twelve years the controversy went on, and £30,000 was lost. Now, the survey was made on the twenty-five inch scale, on which was, and is, based the smaller scales of the survey. The beginning of the survey was a triangulation, and he wished to put some force into the statement. It seemed perfectly simple, but there were undoubtedly a number of people who think they could make a survey without a triangulation. It would be difficult to go deeply into the question, and there was not time for him to explain why they could not make a survey of three or four places and put them together and make maps. They

must take his word for it, it could not be done. In a national survey the truest economy was to grudge no expenditure required to make the triangulation as accurate as possible, as it could be made with the instruments available. It was, of course, not accurate as it was now, the chief instrument being a 36-inch theodolite, made by Ramsden about the beginning of the last century and the work done with this instrument was, as the French said, quite a record of accuracy at the time; but modern instruments had enabled triangulation to be done with still greater accuracy, and the instruments of modern make and much smaller size would do equally good, if not better, work. The principal triangulation of the British Isles was begun in 1784 and finished in 1852, and by means of it the positions of about 250 trigonometrical points were determined. Two principal base-lines and four bases of verification were measured in the course of the triangulation. The former was situated on Salisbury Plain, and on the border of Lough Foyle in Ireland, and some idea of the excellence of the work might be obtained from the fact that on a subsequent occasion, when a portion of the Lough Foyle base was re-measured, it was stated that the only difference in the measurements was only one-third of the finest dot that could be made with the point of a needle. He had, he said, no time to enter into any detailed explanation of the other scientific works which were carried on side by side with the large triangulation, such as the astronomical observations, pendulum, levelling, tidal, and magnetic observations, by means of which triangulation, besides being useful for the survey of merely a smaller area of ground, was extended into a means of determining the figure of the earth and the density of the earth, and, again, to assist in the solution of astronomical and geometrical problems of the greatest magnitude.

They must now proceed, he said, with the question of the reproduction of the maps themselves. This was done at the Ordnance Survey Office at Soton, and the process was a most interesting one. In the library of the office they could see specimens of the maps of the various types, from the biggest scale, which was drawn upon a scale of ten feet to the mile, down to the smallest, and the former, ten feet to a mile or 1-500, was shown every lamp post and every gate, and every step to their houses. The maps were drawn to this scale at one time for every town of 4,000 inhabitants, but it became such a great business that when the question of revision of the survey came to be considered, the Government came to the conclusion that the municipal bodies ought to look after it themselves, and the Ordnance Survey did not revise them unless the corporation asked them to do so, in which case they would have to pay the difference in cost between the revision under the big scale and the Government scale of 25 inches to the mile. The general survey of the whole of the country, which was done at the scale of 25 inches, contained the area of every field, but it did not show the undulations. All the survey maps were done at the 25-inch scale, and the smaller ones were reduced by photography. On the six-inch maps they gave the contours, which showed the relief of the country. Next to the six-inch they had the one-inch, and they showed the contours, and were published in various styles, and in both black and in black and colours. These were the new coloured editions. The one-inch scale was, ten or twenty years ago, considered to be quite a small one, but since the increase in popularity of motoring and bicycling there had been a demand for maps on smaller scales. In the library there was also to be seen one of Ramsden's theodolites, which he had alluded to, and which was the first one used for a grand national triangulation. He then proceeded to explain the two processes used at the Ordnance Office for the reproduction of maps, which were not engraved on copper plates. One was called Heliozincography and the other Vandyke. Both processes depended upon the principle that a bichromated colloid substance became insoluble in water on exposure to the light. The first was the process of making the drawing on the zinc plate itself, then making a tracing on paper in lithographic ink, and transferring that bodily to the zinc. Then photography stepped in, and instead of making a drawing by hand in 1859 the process of Heliozincography was invented at the Ordnance Office. By this means, instead of making a drawing by hand, the original drawing was photographed and a negative obtained. From this negative was made a bichromated gelatine print, and the print was laid down on the plate. The great

advantage of this process to map making was that the gelatine print, having to be developed in water, all accurate scale of the map was consequently lost, due to the shrinking of the paper print. The improved process of Heliozincography by which the negative was printed direct on to the zinc plates without the intervention of any paper print at all guaranteed the fixture of the scale, for this impression of zinc plate was bound to be the same scale as that on the negative. This process was worked out and introduced into the Ordnance Survey Office in 1893. But it was, he said, only just to say that the process had been foreshadowed in theory some years before by General Waterhouse, although it had not been put into practice by him. To obtain the best results of Heliozincography it was always arranged to make the original transfers on enlarged scale, so as to reduce them in the camera. If that was done he felt confident that the process of Heliozincography was the best process at present existing for reproduction of maps which were not too crowded with very small detail. He would remind them that in Heliozincography the zinc plate was made by printing through

a negative. About three years ago a process, now called the Vandyke process, after the name of its inventor, was introduced, by means of which the photographic camera and negative were dispensed with altogether. The zinc plate was prepared by printing through the positive drawing itself, and therefore the subsequent operations were removed. He would not go into further details, because they would see the operations in working order during their visit to the Ordnance Office the next day. He would only wish to point out to their attention that this Vandyke process gave no trouble in the case of reproductions from tracing paper, but they had brought it to such a state of perfection that all their large plans were reproduced by that method, although they were drawn on paper as thick and heavy as Whatman's hand-made paper, weighing 216 lbs. to the double elephant ream. The size of the glass plates used at the office measured 45 by 30 inches, and it would be interesting to any photographer who had a knowledge of the old wet plate process to see the velocity with which practice enabled the operator to coat such large plates with the collodion merely by hand.

### SOME NOTES ON CLOUD PHOTOGRAPHY.

PERHAPS the most remarkable feature of modern photography is the way in which the camera is rapidly replacing the eye of the skilled observer for all sorts of scientific investigations. The record is permanent, the fact it establishes cannot be easily explained away, and deductions based upon it can be reviewed and checked in a manner which was quite impossible when the sole evidence was a sentence or so in an observer's notebook.

Nor is this all. There are ways in which the sensitive film surpasses the retina and renders possible innumerable discoveries which, without it, would have been beyond our reach. I need only mention the marvellous revelations which the camera has made in the realm of astronomy and astrophysics. The camera, by prolonged exposure, can see things which no telescope, such as we can imagine can ever render visible to the eye. Photographic action is cumulative, but if an object is not bright enough to affect the nerve endings in the retina within the tenth part of a second it will never be visible at all.

In other branches of science the camera has rendered invaluable help by enabling us to record events which are so brief or so rapid that the eye cannot follow them, such as the analysis of the gallop of a horse, the study of the waves of air before a flying bullet, and even the movements of the waves of sound.

The cinematograph has given us yet another power, which has not been much used, but which might yield most instructive results. That is, to employ it for the movements and changes which are too slow to be adequately realised. For instance, if a plant, such as a sweet pea, were photographed from the same point of view at suitable intervals, and the photographs were then combined and projected on the screen in rapid sequence, we might watch the growth and development of the flower, the processes by which the leaves unfold, and see the tendrils twisting round the supporting sticks. The same method might be applied to the growth of a man, by combining a series of portraits taken under similar conditions, and, if the object were to point a moral, the actual debasement of the drunkard, or the restoration of the invalid to health and vigour by the use, let us say, of a patent food, might be witnessed by an audience in the time taken by the exhibition of a single film.

All these properties of the photographic film meet with applications in the realm of meteorological science, and the opportunity of reaching photographers by addressing this convention is too valuable to be missed. It is not necessary to ask that whenever any extraordinary event occurs a record shall be taken. Cameras are so numerous nowadays that some one who uses one is almost certain to take pictures of any extraordinary flood, any remarkable hailstones, or damage by wind and storm. But those who take them do not often send copies where they may be most useful, which is to the secretary of the Royal Meteorological Society, 70, Victoria Street, Westminster. There are, however, two branches of meteorological inquiry in which there is much to be done, and much that cannot be done without a considerable increase in the number of observers who will use their photographic apparatus for that end.

The phenomena of a lightning discharge have been studied photographically for about fifteen years, but there are still several points

upon which agreement is by no means general; while certain forms of lightning, such as the rare phenomenon called ball lightning, have been repeatedly described, but have not yet been photographed. Lightning is, of course, photographed at night. Rapid plates should be used, and the largest aperture the lens will bear. The camera should not be held in the hand, but should be fixed to its stand, or to some firm inanimate support. After adjusting the camera in focus for a distant object, exposure should be made in the direction in which the flashes are frequent, and as soon as a flash comes in the field of view the plate should be changed. This last is important. If a flash prints its image on the plate, and the diffused light of a subsequent flash, or from any other source, is allowed to fall on the same place, the image of the first flash is liable to be reversed, in accordance with the curious photographic phenomenon which I described to the Physical Society of London in 1889. Sometimes it happens that the flash is not reversed, but simply obliterated, but reversal is the rule if the diffused light falls on the plate subsequently to the impression of the flash image.

With reasonable care and luck, lightning photography is quite a simple thing, and the resulting picture may be most interesting and valuable from a scientific point of view, and a print should be sent to the Royal Meteorological Society. It is not possible here to even mention the numerous points which might be cleared up by a large number of photographs, but, to give an instance, if the camera is firmly fixed and the time of each flash is noted, it might well happen that two or more pictures of the same flash from different points of view could be identified, and its whole form in space could be then determined.

The camera must not be exposed through a closed window, but from the shelter of a verandah, or an open window. Probably all people feel a little nervous when there is a heavy storm, and the feeling is excusable, for every flash which strikes the ground has its billet somewhere, and a certain type of discharge pays no attention to conductors or to the relative heights of buildings and so forth. But the interest of trying to catch the portraits of the flashes has a wonderfully soothing effect. If it is possible to conduct the observations from the inside of a galvanised iron building the operator may be undisturbed, for it is probable that the inside of such a structure would be absolutely safe.

The second direction in which the co-operation of photographers might yield valuable results is in the study of the rapid changes of the thinner and higher types of cloud. It is not an easy investigation to embark upon, but is much easier than is generally supposed.

A good many years ago, I wanted a series of typical lantern slides of cirrus in order to illustrate a course of lectures, and as there were no such things in the market, determined to get them. I tried in turn rapid plates, ordinary plates, small apertures, and coloured screens. Sometimes I was lucky enough to get a printable result, but the plates were generally wasted. Over-exposure was the rule, and over-exposure of so pronounced a type that I was led to try the slowest plates I could obtain—namely, those sold as photo-mechanical. With these a short exposure and small aperture gene-

rally gives a result which may be carefully developed into a useful image. But the actinic conditions vary immensely with the time of day, the season, and the weather conditions, so that no rule can be given except that which comes by practice. A deep clear blue sky as background, allows a much longer exposure than one in which everything is a glittering silvery grey. Again, much depends on the position of the sun relative to the cloud, the longest exposure being allowable when the sun is at right angles to the cloud.

Since it is practically impossible to be sure of the exposure, I have found it necessary to adopt a tentative method of development, using the old fashioned pyro and ammonia. The plate is first soaked in pyro, with about one quarter of the normal quantity of ammonia, and rocked for about three-quarters of a minute. If nothing shows in that time, a further quarter of ammonia is added to the developer and the plate again rocked, and so on, until the highest lights appear. When this happens they are allowed to gather density, and the plate is watched so that more ammonia can be added if there seems danger of a hard negative, such as would give a chalky print. With very thin gossamer clouds it may be necessary to resort to intensification.

It is thus fairly easy to get richly detailed pictures of very thin cirrus and cirro-cumulus clouds, but the whole process becomes much easier, and, therefore far more certain if the light is reflected into the camera from a black mirror placed so as to make an angle of about 33 degrees with the optic axis of the lens. This more than quadruples the exposure, and the result is denser and richer negatives.

Now, there are two distinct purposes for which cloud negatives may be wanted. To show their forms and changes of form; and for pictorial effect, such as for printing skies to land and seascapes.

We are at once confronted with a difficulty. If nature were reduced to monochrome, as it must be in a photograph, the extremes of light and shade are far wider apart than they can possibly be in any print. Indeed, this difficulty is not restricted to pictures in monochrome. Even in works by the greatest landscape artists the contrast between the highest light and deepest shadow is vastly less than it is in the scene he attempts to delineate. It is like trying to reproduce a tune within a quarter of the compass of the original.

To represent the form of a piece of sculpture in such a way as to give a correct idea of its modelling we need to use a large part of the available scale of light and shade. Similarly, if we would record the full shape of a cloud, we also need a gradation of light and shade which leaves us only a narrow margin of shadow for the less luminous landscape. The difficulty is increased by the substitution of a monochromatic picture. We have no means of contrasting the shining white cloud, every bit of which is brighter than a corresponding part of the full moon, with a clear blue background, except by representing the sky as dark.

If, then, our object is meteorological, we must use our scale freely, and be patient when the uninitiated suggest that the pictures were taken by moonlight. For pictorial effect, to be used in combination with landscapes, we need thinner and flatter negatives, and must be content to lose many of the finer details of the sky in order to get the nearest possible approach to a satisfactory whole. Fortunately, the two things are not incapable of being simultaneously done. Negatives which are failures from a meteorological point of view, are often exactly right for combination work, and other negatives which can give vigorous prints full of detail often serve excellently for landscape work if lightly printed.

There is, however, another difference. To get isolated studies of clouds the camera should generally be tilted up at a more or less high angle. Such negatives cannot be properly used for printing a landscape, which would be taken with the camera looking horizontally. The perspective would be totally different, and the result of a combination in many cases ridiculous. For printing into a picture, the cloud negative ought to be taken with the same lens, and with the camera, at the same inclination. The only difference strictly allowable is that the rising front may be raised to its limit, but the level of the horizon should be marked on the negative at one side, and in using it for printing-in care should be taken that this mark coincides with the landscape horizon.

A picture of an open landscape, such as a rolling moor, becomes an entirely different thing when a suitable sky is printed in, but it must be a suitable sky. I remember once seeing in a photo-

grapher's window a fine large picture with bold cumulus cloud but unfortunately the sunlight fell from the left upon the landscape and from the right upon the clouds, and the sky horizon was about level with the bottom of the whole picture. The effect was eminently unreal, even to the most thoughtless.

High clouds of the cirrus type might be introduced into any small picture, and even more beautiful results may be produced by using some of the exquisite alto clouds, but if heavy cumulus should be introduced their shadows have to be reckoned with.

There is no need to say more on the pictorial aspects of cloud photography for printing on paper, or into landscapes. But if the object in view is a series of lantern slides, then it may be interesting to some to give details of a simple device whereby the white cloud can be shown with a background of blue sky. Cirrus and some of the alto clouds have no grey shadows on them. They are white threads and flecks, showing more or less of the blue background through.

Some years ago it occurred to me to try the ferro-prussiate process for such clouds. I had in stock a quantity of quarter-plate lantern plates and photo-mechanical plates which had been left in a damp loft for several years, and gave stained negatives. I took some of these, dissolved out all the silver salts with a strong hypos bath, washed the gelatine films for about twenty-four hours, and then resensitised them by soaking for half an hour in a ferro-prussiate mixture, such as would be used for paper. They were then rinsed under a tap to remove iron salts from the surface, and dried in the dark. Some of them showed crystalline figures, due to an excess of iron. These were rejected. But the greater number were freed from this defect. When apparently dry, they were heated to about 100 deg. Fah. over a closed stove to ensure perfect dryness, and after cooling, were exposed under ordinary negatives. After exposure they were fixed by washing, and the density adjusted by the use of exceedingly dilute hydrochloric acid. As thus obtained, the colouring matter was, of course, Prussian blue, which has rather a greener tinge than true sky blue. But on washing in water containing a trace of caustic alkali, part of the blue pigment is changed into a violet substance, and part even into the red hydroxide of iron, the effect of which is to neutralise the greenish tinge. It is necessary, however, to print the slide so that the sky is too deep a blue to begin with, as the toning is also a powerful reducing process. For this reason also the alkali must be excessively dilute. The finished slide should look a little strong, or the detail will be lost when it is projected on the screen.

The final heating of the plate is very necessary, as the iron compounds are deliquescent, and are liable to soften the gelatine, and cause it to stick to the negative, with disastrous results. Much better effects could probably be produced by the use of carbon tissue coloured with cobalt blue, but no such material seems to be obtainable.

So much, then, for the pictorial side of cloud photography. What is there to be done from a scientific point of view? No easy task, for it is nothing less than the taking of series of photographs of some of the higher clouds so that their changes of form can be traced step by step. If we look up at a patch of cirro-cumulus, and then after a few minutes look again, the detail is often utterly different. Most of all is this the case with the beautiful wave and ripple clouds.

In any such event, a series of a dozen or so of pictures, taken at intervals of one or two minutes, would show the processes by which the changes are effected, and would be likely to prove of the greatest interest and value. Storm clouds, the clouds attending a whirlwind or a waterspout, should be similarly traced. Even the cinematograph might be pressed into service to take a series. In some cases, such as a whirlwind cloud or waterspout, the exposures should follow one another at intervals of, say, a second, or half a second; while for tracing the movements of wave clouds the intervals should be much longer.

A print from such a film would be shown at the usual rate, with the result of quickening the movements of nature, so that they would be easily realised and understood, and the series of views when studied separately would tell more of the mechanics of these atmospheric disturbances than years of thought and observation without the aid of the camera.

Photography is too often regarded merely as a pleasant pastime,

the camera as a costly toy, and it is the object of this brief note point out some few directions in which, without straying from pursuit of what is strange or beautiful, its marvellous powers as a scientific tool may be pleasantly exercised.

The seekers after knowledge have passed through the age of the microscope and telescope, followed by the age of the spectroscope,

but the present becomes, year by year, more and more the age of the photographic camera. No laboratory, no observatory is complete without it. With it, and particularly with its more elaborate and costly forms, there are many avenues of research, by following which important discoveries may be made, and meteorological photography is but one.

ARTHUR W. CLAYDEN, M.A.

### COMBINATION PRINTING.

PRESIDENT, LADIES, AND GENTLEMEN.—Far from seeking the hour of addressing the members of the Photographic Convention, I tried hard to persuade the powers that it was an ill-advised thing to do, more especially as the subject upon which it was proposed should address you is one upon which I have nothing new to say; that the subject of combination printing should have been set out and given to me is of itself a somewhat gratifying fact. I have been connected with photography sufficiently long to have possessed an almost entirely reversed feeling with regard to that particular phase or application of photography which we commonly call the "pictorial." Time was, and not so very long ago, that the aims and intentions of the pictorialist were, by the majority of photographers, so much misunderstood that if a photograph did not illustrate the maximum qualities possible by the particular process, its character was set down to the inefficiency of its author. It mattered not that the producer of the print claimed that, as the picture was, so he intended it to be; it mattered not that he asked to be allowed to employ just as much or as little contrast as he thought best; it mattered not that he definitely and deliberately departed to the image just the degree of definition which he thought it; it was constantly said that an example of anything less than maximum contrast, maximum definition, maximum brilliance, was merely evidence that the author of the print could do no better on if he would. In those days—comparatively a few years ago—was with the application of photography to pictorial ends—though a man walked leisurely for enjoyment, and were ridiculed and condemned as being incapable of running even if he wished.

All this, which was due to misunderstanding, is now, happily, changed, and simultaneously with the development of a more tolerant and broad-minded view in other things besides art, greater liberty has, by common consent, been granted to the photographer; and whilst those who in former times had to bear the ridicule and the mortification of being misunderstood, naturally feel gratification at now being recognised and appreciated, they may do well to remember that they and workers of their class have, perhaps unconsciously, made such better recognition possible.

I submit that in the early days of the new pictorial movement, much of the misunderstanding on the part of the unsympathetic, was very largely due to the fact that so much of the work put forth tried to justify itself, however good the intention of its authors may have been, but as greater executive skill has been acquired, and a better acquaintance with the appearance of nature has been acquired, the productions of the aspiring pictorialist has been in less need of an apologist and an interpreter, and so has won toleration, if not absolute approval. This applies as much to what is understood by the term combination printing as it does to the deliberate suppression of excessive detail or to unnaturally strong contrast.

I suppose that to everyone the term combination printing at once conveys the idea of employing two or more negatives for the production of one result, and often when such combination has been effected the principle has been condemned on account of the ineffectual nature of the result. It was pointed out that the relative tones of the various parts were not true to nature, that the joins of the various parts showed and betrayed the method employed. Even the simplest application of combination printing—namely, printing a sky from one negative and a landscape from another, thus producing a single combined picture, was condemned—and why? Most often because it was said that an unnatural effect was almost certain to result.

Given a case in which cloud and landscape from separate negatives have been so skilfully brought together that no suspicion of the composite nature of the picture is awakened, then unless special information be volunteered it is difficult to see how objection can be made.

This may sound contrary to the code of ethics by which every good citizen directs his life, because it is equivalent to saying that the condemnation of an act contrary to established law exists only in its being found out. In the present case, however, I would

suggest that there is no law, and therefore the condemnation of combination printing is in its being done badly, and then it not only betrays itself (that is not an important matter), but it produces an unpleasing effect, because the moment anything in a picture sets us thinking of *how* it is done, the æsthetic pleasure in that picture is interrupted, if not, indeed, wholly destroyed. I think the whole idea of principle being involved, the resentment arising from the feeling that in combination printing a deception is being practised, arises from the fact that in earlier days every piece of photographic work was shown with a view to demonstrating what photography can do, and in such case it is obvious that to borrow a piece from one negative and add it to another would have been equivalent to making a false declaration; but the case to-day is this, that if by combining parts of several negatives one can get more nearly a representation of one's personal impression, and yet one could not do it so well by any other means than photography, it shows that photography has been employed deliberately by one who had a desire to express himself of the manner in which things impressed him personally, and, having no means at his disposal, no method within his power of doing so, he has employed just so much of the photographic process as he needed, and no more, because the desire to express himself, and not an exposition of a process or personal skill, was paramount.

But perhaps you may say that such arguments as I am advancing are unnecessary because you are already quite willing to grant the legitimacy of combination printing, and indeed of many other methods which the photographic purist of a few years ago would have utterly condemned. Well, then, I should like to utter a caution against our too readily consenting to practices which in themselves may be quite justifiable, because they may involve a degree of personal knowledge which few, if any, possess.

Having seasoned ourselves into admitting the legality of combination printing, there is a danger of our forthwith piecing together a portion of this and a portion of that, and the result seems good to us; besides, we are proud of our cunning and skill. Thus shall we be falling into the same error that an earlier generation of painters fell into who painted always in the studio according to tradition, until the Gospel of Naturalism taught them to seek fresh inspiration for every fresh picture by painting it out-of-doors, and painting it direct, thus having opportunity of corroborating the ideas which previous observation had engendered.

Where is the photographer who has had even as much training in the observation of nature as the art student receives within the first few months of his novitiate. How, then, can the photographer trust to his own knowledge, his own ideas, as to whether this or that portion suits another portion.

It is because I feel that so few photographers have the requisite intimacy with nature to enable them to avoid the pitfalls in which the practice abounds that I should hesitate to advise any to resort to it. It is because I feel so uncertain myself, because I can see how great are the possibilities of error, and how easy to commit them unwittingly, that of late I have myself entirely ceased to use combination printing.

Few photographers have sufficiently keen perceptions, few can discern a discrepancy when the camera has given them a representation sufficiently like to be recognisable. How many of us here can be quite sure how much darker or how much lighter a shadow should be when compared with the dark side of the object which casts the shadow, and for want of that knowledge, and because even in skilful hands the photographic plate does play us false in the matter of relative tones. Such intimate knowledge of physical facts is eminently important, and when possessed it would prevent the public display of many a photograph which has brought discredit upon its producer, and contumely on the craft to which all here are so interested.

Still, despite the danger, no doubt some intrepid one will desire to

know how the combination of parts of several negatives can be brought about, but in this connection I am afraid I may incur your displeasure.

It is not very long ago that I demonstrated somewhat fully the two methods which I have myself employed before the London Camera Club, many of the members of which are present at the Convention, whilst still more recently I have had something to say of the matter before the Southampton Camera Club and other societies; and whilst I have nothing new to add, still I felt you might expect something of a practical demonstration; but when I saw this hall I realised that it would be impossible to show an audience anything like actual manipulations; furthermore, such a thing would occupy a very considerable time, so not because I would spare myself trouble, but because I deem it more advisable to omit anything like practical examples.

Whatever means one resorts to for combining parts of several

negatives, there are but two main rules to observe. Firstly, there must be a system whereby such accurate registration of the successive parts to be printed that it will not be possible for anyone to criticise the principle because ineffectually carried out; and, secondly, the practice must be founded upon such ample knowledge of nature and such fastidious care that it must appear as though it could have been otherwise in nature, and if you realise how difficult this is I am not sure that you will not come to the conclusion that combination printing is only for the very few.

Ladies and Gentlemen, I would fain win your approval, if not your applause, and fearful that the matter of my very brief discourse may fail to interest, as I am conscious of an inefficient manner of delivering, I at least hope to meet with your favour by complying with the words of the program and burdening you with only a short paper.

A. HORSLEY HINTON

On Friday the excursion to Winchester and St. Cross was very largely attended, but photographic work was somewhat marred by continuous rain during the afternoon, and in the cathedral by the very considerable portion of the structure undergoing repair.

In the evening a paper was read by E. J. Wall on "The Present Status of Colour Photography" (which will appear in our next), and examples of work shown by triple projection by the kindness of Sir Wm. Abney, who was unable to be present, and the ordinary three-colour slides by the Lumière A. Company, Messrs. Sanger

Shepherd, Dr. Albert Norman, Miss Acland, Messrs. E. T. Butler, Pfenninger, Alfred Watkins, Captain Lascelles Davidson, together with Lippmann results by Mr. Alfred Senior, Wood's diffracting colour photographs lent by Messrs. Newton and Co., the colour carbons by the Rotary Photographic Company, Kromske by Messrs. A. J. Newton and C. Phipps Lucas.

Subsequently a brief show of "cinematography in colours" was given, with a few explanatory remarks by Captain Lascelles Davidson and Mr. W. Friese Greene.

### THE KEY TO THE CONVENTION GROUP.

With this issue of the "British Journal," we give the key to the Convention Group reproduced last week. The short time between exposure and publication last week—less than twenty-four hours—did not permit of the key being prepared in a form convenient for reference, although it would have been possible to present a key made by the photographic method, which was adopted to secure the names of those present. As the method may be of use to others having to take large groups, we herewith reproduce the print, showing how the names were obtained. A glance at the reproduction will explain matters. Each member of the group was provided with a card seven inches square, one side of which was the request to (1) sign the name, and (2) hold the card before the face for a second exposure. On the other side of the card was a large number, and the

whole of the names are thus obtained at once. To avoid increasing the size of the card the numbers are kept to two figures, and a large group; then one of ninety-nine provided with a second series of cards from one to ninety-nine, but distinguished by stars, as seen in some of the figures. The only drawback to the plan is the time needed to distribute the cards, which may be such as to cause one or two people to leave before the second exposure is made. Also the cost of getting the cards is altogether too high to make it worth while for a photographer to get them printed for one or two groups only. But we should think that one of the large houses might very well place a series of, say, 1-99 and 1\*-99\* on the market in 7-inch squares, the blank side being available for the photographer's printed directions.

# THE ACTION OF ALUMS AND ALUMINIUM SALTS ON GELATINE.

Alums possess the property, as is well known, of hardening gelatine and raising the setting point of aqueous solutions. This phenomenon does not appear to have been precisely studied, and it is summed to be analogous to the insolubility produced by chromium salts. We decided to examine the question, and to study especially the following points.

1. The influence of the nature of the aluminium compounds employed to raise the temperature of the setting point of gelatine solutions.
  2. The influence of the quantity of these compounds and the concentration of the gelatine solution on the setting point.
  - 3 and 4. The constitution and properties of the alumed gelatine.
- The Influence of the Nature of the Aluminium Compounds on the

## Setting Point.

Besides aluminium sulphate and the potash and ammonia alums, the effects of which are already known, we have studied the action exercised by the chloride, bromide, and nitrate of aluminium on aqueous solutions of gelatine.

We have been able to prove that these salts practically raise the setting point with the same proportion of aluminium.

The setting point of solutions of gelatine with the addition of aluminium salts is more difficult to determine than without the same. For the latter pass practically from the liquid to the solid state in about one degree, as the mass in cooling arrives at a pasty stage very near the setting point. In the presence of aluminium salts, on the other hand, the solution remains pasty for a very long time before becoming solid; the mass is then viscous in certain cases where the temperature is raised 15 degrees above the setting point. In other cases the viscosity varies with the salt of aluminium employed, and it increases as one approaches this point. We consider that the setting point is reached when on stirring the mixture with a thermometer and withdrawing the latter vertically, the small quantity adhering to the thermometer remains solid without dropping.

The same effects may be produced, perhaps slightly weaker, by means of alumina *in statu nascendi*, obtained by the action of equimolecular quantities of ammonia and alum. An excess of ammonia stops the action of the alumina. The basic salts formed by the exact neutralisation of alum by ammonia behave in the same way as a non-neutralised alum. Finally, the alkaline aluminates exert no influence of the setting point.

## The Influence of the Quantity of the Aluminium Compounds on the Setting Point.

In working with a 7.5 per cent. aqueous solution of gelatine, we have found that very small proportions of alum or salts of alumina sensibly increase the setting point. The temperature increases a degree with 0.107 gm. of alumina per 100 gms. of gelatine, and as the proportion of the aluminium compound increased it was found that the setting point was raised till the proportion of alumina was approximately 0.64 gm. per 100 gms. of gelatine. The setting point, then, is about 6 degrees higher. This maximum effect is produced by adding to 100 gms. of gelatine the following weights of the various salts, which correspond to 0.64 gms. of alumina:—

Potassium alum, $Al_2(SO_4)_3 K_2 SO_4 24H_2O$	6.0 gms.
Ammonia alum, $Al_2(SO_4)_3 (NH_4)_2 SO_4 24H_2O$	5.6 "
Aluminium sulphate, $Al_2(SO_4)_3 18H_2O$	4.2 "
" chloride anhydrous, $Al_2 Cl_6$	1.6 "
" nitrate, $Al_2(NO_3)_6 15H_2O$	4.3 "

If these weights are exceeded the effect of the aluming is not increased.

When the strength of gelatine is altered it was found that the maximum of the setting point varied to an equal degree. It is 7deg. for a 12 per cent. solution of gelatine, 3.5 deg. for a 5 per cent. solution. Whatever may be the concentration of the gelatinous solution, it is always the same amount of alum which produces the

maximum effect, that is, 6gms. of potash alum=0.64gm. of alumina per 100 gms. of gelatine solution.

## The Composition of Gelatine Modified by the Salts of Alumina.

If a thin film of gelatine and alum is coated on a sheet of glass and then washed till the water shows no trace of sulphuric acid, it will be found that the alum is disassociated, and that the sulphuric acid and the potassium are entirely eliminated; it is the alumina alone that is fixed.

When sheets of gelatine are immersed in a solution of aluminium sulphate and the latter titrated, it will be found that the solution will be impoverished, and that the gelatine has fixed the alumina. On quantitatively estimating the alumina and sulphuric acid in this solution before and after immersion of the sheets of gelatine it will be found that the ratio of the weights of these substances remains practically constant.

The immersed gelatine appears then first to fix the alumina compound in the form of  $Al_2(SO_4)_3$ , which the treatment with water disassociates, the alumina alone being retained by the gelatine.

It was now to be determined whether the alumed gelatine ought to be considered as a true chemical combination. For this purpose a 7.5 per cent. solution of gelatine was divided into equal parts, and increasing quantities of alum were added. These mixtures, coated on glass, were dried, and then submitted to prolonged washing in running water. The film stripped from the glass was again washed in water till the washing water showed no trace of alumina or sulphuric acid. The results were then dehydrated by washing with alcohol, desiccated, powdered, and analysed. The following were the results obtained:—

## ACTION OF THE ALUMS AND ALUMINIUM SALTS ON GELATINE.

Test No.	Quantity of Alum added to 1,000 Parts of 7.5 % Gelatine Solution.	Quantity of Alumina added to 100 Parts of Gelatine.	Quantity of Alumina fixed by 100 Parts of Gelatine (after washing), mean of several tests.	Quantity of Sulphuric Acid retained by 100 Parts of Gelatine.	Ash per 100 Parts of Gelatine.
1.	Check Nil.	Nil.	Nil.	Nil.	0.5
2.	1.85	0.23	0.47	" "	0.906
3.	4.75	0.59	2.09	" "	2.7
4.	6.5	1.18	2.6	" "	3.25
5.	19	2.36	2.9	" "	3.5
6.	25 (1)	3.1	3.6	" "	4.18
7.	38	4.75	3.56	" "	4.03
8.	75	9.4			

In the tests 1-5 it was eliminated from the Gelatine in the washing, which explains the increase in the proportion of alumina to the initial proportion.

The tests prove that the quantity of alumina retained by the gelatine increases with the weight of alum employed till the gelatine has fixed 3.6 per cent. of alumina; beyond this point, whatever may be the proportion of alum used, the weight of alumina contained in the gelatine remains constant.

It would seem that in this case we have a true chemical combination.

It should be noted that the greatest increase of the setting point of the alumina gelatine is obtained when that gelatine contains 0.6 per cent. alumina, does not correspond with the greatest fixation of this substance.

## The Properties of the Alumed Gelatine.

The alumed gelatine having fixed the maximum of alumina, that is to say 3.6 per cent., presents the same appearance as ordinary gelatine, but it swells much more slowly than the latter in cold water.

Very dilute acids appear to have no action on the alumed gelatine at ordinary temperatures; but they disassociate it when they attain a certain concentration.

The caustic alkalis and ammonia, even in feeble proportions, appear to destroy the combination and reduce the gelatine to its original condition. The alkaline carbonates act like the caustic alkalies, but act less energetically.

The preceding tests allows us to draw the following conclusions.

1. That different salts of alumina and nascent alumina possess, like alum, the property of raising the setting point of aqueous solutions of gelatine. This property seems to be entirely due to the action of alumina; the same results being obtained with very different quantities of the various salts, when they contain the same weight of alumina.

2. Of all the salts of alumina, alum produces for equal weights the least increase of the setting point, in consequence of its small proportion of alumina; for the opposite reason anhydrous aluminum chloride produces, on the contrary, maximum effect.

3. The setting point of aqueous solutions of gelatine increase proportionately to the quantity of alumina that is added, till it corresponds to 0.64 gms. of alumina per 100 gms. of gelatine, whereafter it may be the salt of alumina employed. Above this quantity the setting point remains constant and then decreases.

4. The setting point varies with the concentration of the solution of gelatine.

5. Gelatine appears to fix a maximum quantity, about 3.6 gms. of alumina per 100 gms. of gelatine, and to give up to water the alumina or salts which are combined with this base. It appears to form a definite compound.

A. AND L. LUMIERE.

## SELECTIVE FOCUSING IN PORTRAITURE.

THE reproduction of a portrait in our contemporary the "Camera" leads its author, Mr. Felix Raymer, a well-known portraitist and writer in the United States, to explain the methods adopted to assigning different degrees of definition to the various portions of the photograph. As the method followed is one which may be easily applied, with variations, to other cases, we may reproduce a small portion of Mr. Raymer's explanation:—

"I will now give directions for focussing on this portrait as the method was followed out. First, the lobe of the nose was focussed on. Why? For the reason that it is nearer than any other part of the face, and, being nearer, it should have its proper place or weight in the picture, which would be nearer to the beholder of that picture. In addition to this, it must be remembered, that the light is concentrated at that part of the face as strong, if not stronger, than any other part of the face. The strongest concentration of light should receive the strongest concentration of focus to be in perfect harmony.

"Next, the side swing of the camera was used until the near or light shoulder was brought into focus, which at the same time lessened the distorted effect of the far or subordinated shoulder. Without the use of this side swing the near shoulder would have been out of focus, and so would have been the far shoulder, so that the focus would have come through the central parts of the drapery, making the near and the far shoulders have a distorted effect. The near shoulder being the one at which the light is concentrated, should be the one at which the focus is concentrated, so that the swing is used until that effect is secured. Now we take a look over the entire field. We see that the centre of the face is focussed

at the parts that are accentuated by the light, but as the eye travels backward to the back of the head, it does so over a field that receding or going from us. Is this right? Certainly, for it is what we call perspective or distance. If this field does not recede it will be a flat field or one that has no distance. To see the effect of these two pictures, focus your lens on a subject as I have described, and make a negative, then leaving all else the same, insert a diaphragm that will bring the back of the head in focus and make another negative; make prints from both and compare them, and see which possesses the greatest amount of roundness.

"It is this difference in focussing that makes one man's work better than another's many times; not always, of course, but I am sure in most cases. It is apparently a small matter, but in reality the whole picture depends upon the effect of the result, and it is often spoiled by the operator using a lens not intended for portrait work. I have visited numbers of studios and found the operator using a small R.R. lens working at  $f/8$ , and he would wonder why his pictures do not look like some of the best work made. The reason is that the R.R. lens cuts too deep for pictorial effect in portrait work; it makes too flat a field, or too near the subject in all parts of the picture. Another thing many cannot understand, and that is why I can give so little exposure on the negative I make at the conventions, and they have to give so long a time to theirs at home, when the light they have is as large as the one I may be using at the convention. This is accounted for by my lens being a portrait lens, and working at a larger aperture than theirs, which is an R.R. or symmetrical working at a much smaller aperture."

## Photo-Mechanical Notes.

### The Printing and Allied Trades Exhibition.

THE Exhibition, opened by the Lord Mayor on Saturday last, and remaining open until July 28, is not only full of interest for the photographer, as showing how important a place photography is taking in the graphic arts, but is especially important to the photo-engraver, since most of the leading firms are exhibiting their work, and the material dealers take this opportunity to show their novelties. Dealing with the photo-engraving firms in alphabetical order, the Anglo-Engraving Company show some large three-colour work, as well as much two-colour and ordinary half-tone. They show the originals side by side with the reproduction so that comparison can be made. The Art Reproduction Co. show a lot of specimens, including coloured photogravures. The Cox Illustrating Co. show many specimens, and also examples of their metallic overlay. Messrs. Dent and Co. have an attractive stall again, with the original and reproduction in many sizes, and a new method of preventing the wood mount from warping. Carl Hentschel, Limited, have a good display, especially of Colourtype. Messrs. Marshall have a tasteful show in the gallery. The Press Etching Co. have a stand with many specimens; and John Swain and Son, Limited, are near the main entrance, with a show of specimens of half-tone, three-colour, wood engraving, and electrotypes.

Hunter's, Limited, have a big stand showing a complete range of supplies for printer and photo-engravers, the principal novelty being the Mark Smith patent etching machine, which bids fair to take away with the old rocked-tub method of etching.

Penrose and Co. also have a show, with their latest form of screen camera. As novelties, they show an enclosed arc lamp for three-colour work. This contains three carbons which can be changed instantaneously, so that red, green, and blue light respectively can be used without any extra trouble. They have also introduced and exhibit a neat little appliance for ruling up three-colour plates in exact register without loss of time, which should prove a boon to the three-colour block maker.

The L.C.C. School of Photo-Engraving have a large exhibit in the gallery, comprising specimens of students' work in all branches and several frames showing the progressive stages in photo-mechanical work. There is also in the gallery a large loan collection, got together by St. Bride's Institute, illustrating the history of the printing art, and here there are specimens shown of almost every imaginable process.

### A German Book Production School.

We have received from the Royal Academy of Graphic Arts at Leipzig, a volume containing a history of the school and details of the courses of instruction, together with many reproductions of the student's work showing the wide range of the studies there, which cover book production in all its branches, including even ordinary

portrait photography. There are examples of drawings, reproduced half-tone, line, and three-colour original wood engravings, lithographs, wood engravings, type settings, and bookbinding designs. The get-up of the little book is, on the whole, exceedingly tasteful, and it is pleasing to see the half-tones printed on something less glaringly white and shiny than usual.

Many will hear with regret of the death of Mr. Edward Bierstadt, New York. He was born at Solingen, Germany, in 1824, but early migrated to America, and established himself in New York in 1870 for the production of Albertypes. In 1880, he turned his attention to three-colour work, and it is related that in making the plates, a red screen was exposed forty-four hours. His first photograph in colours from life was made in 1894, the exposure requiring ten minutes. Mr. Bierstadt's name has come prominently before the public in recent years through his having produced in company with Geo. B. De-Vinne the process of making mechanical overlays for half-tones which bears their joint names.

# PHOTO-MECHANICAL PATENTS.

**PHOTO-MECHANICAL PRINTING.**—No. 15,926. Improvement in photo-mechanical printing. John William Ippers, 65, Chancery Lane, London. (Date applied for under Patents Act, 1901, July 14, 1905, being date of application in the United States.)

**PRINTING PLATE ATTACHMENTS.**—No. 15,270. Improvements in or relating to means for attaching half-tone process plates, fine-line etchings, and the like to the stereotype plates of rotary and other printing machines. George Allan and Arthur Rowland Byles, 33, Chancery Lane, London.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for patents have been made from July 2 to 7:—

**ENLARGING APPARATUS.**—No. 15,113. Improvements in photographic enlarging apparatus. Herbert Holmes and Houghtons, Limited, 88, High Holborn, London.

**MOUNTS AND FRAMES.**—No. 15,359. Improvements in mounts, frames, or wallets for supporting pictures or the like. Frédéric Eugène Vignerot, 3, Brown Street, Market Street, Manchester.

**CAMERAS.**—No. 15,437. New or improved apparatus for use in connection with photographic cameras. Claude Horace Gaggero, 57, Arcadian Gardens, Bowes Park, London.

**TESTING LIGHT FILTERS.**—No. 15,455. Improved testing device for photographic light filters. Edgar Clifton, 25, Newman Street, London.

# COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PRINTING PLATES.**—No. 5,780, 1905. This invention relates to negative plates, and has for its object the making of plates, from which the image of cut or incised lines, produced by etching, may be printed on any sensitised surface, the lines showing varying degrees of light and shade. The claims made are (1) the process of preparing a plate for photographic printing, which consists in placing a transparent or translucent plate coated with a transparent or translucent but non-actinic surface or ground over the subject to be etched, outlining the subject looked at through the plate by lines or incisions made in the aforesaid surface or ground, and then wholly or partly filling said lines or incisions or some of them with colours having different actinic properties substantially as described for the

purposes specified; (2) a prepared plate for photographic printing, having a transparent or translucent but non-actinic etching surface or ground, substantially as described for the purpose specified. William Jay Little, of Newton, Massachusetts, U.S.A.

**EXPOSING FILMS.**—No. 26,191, 1905. This invention relates to the exposure of films and plates inserted into light proof envelopes, and the latter may be pulled out of the case through a slot, and the film or plate is retained in the case. In Fig. 1 the case chamber is designated *a*. This chamber is intended for the reception of the exposed films, *b*, and is shut off from the exposing chamber by the slide, *c*. The slide, *e*, is acted on by springs, *d*. By the yielding support of the slide, *c*, it is

FIG. 1.

rendered possible to use the same case for plates and for films. The exposing chamber is outwardly bordered by the cover-frame, *e*. *f* is a bar fixed to the lateral frame-parts of the case. The cover-frame is provided with a rod, *g*, which, when the case is closed, extends with its lower edge more closely to the surface of the slide, *c*, than the upper surface of the bar, *f*. *i* is the light-proof envelope of the layer-carrier and *k* the layer-carrier itself. *l* is the lower closing-slide for the case. The light-proof envelope, *i*, is closed at both ends. The closed ends are folded over, as shown in Fig. 2, so that the position of the film in the envelope is shown by the folding of the ends. The package can, therefore, at any time without difficulty be so inserted into the case that the edge of the film adjacent to the bar, *f*, is not engaged by the bar, *g*, and does not lie above the bar, *f*. When a package has been inserted into the case, for which purpose the cover, *e*, of the case is opened, and when an exposure is to be made, that end of the package which is at the side of the case opposite the side at which the rod, *f*, is situated, is severed, in order to open the light-proof envelope. When this has been done the other end of the envelope, which projects from the case at the end supporting the bar, *f*, is pulled. The lower edge of the rod, *g*, then forms an abutment for the edge of the film, *k*, so that the latter cannot pass

FIG. 2.

through the slot in the case, whereas the light-proof envelope can move out of the case along the sinuous path indicated in the drawing. As soon as the envelope has been pulled off the film the latter can be exposed. After the exposure the film is allowed to drop into the case-magazine, *a*, by opening the slide, *c*. When said magazine contains a sufficient number of films it is opened by drawing out the slide, *l*, and the exposed films, *b*, are removed. 1. The method for exposing light-sensitive layer-carriers contained in light-proof covers, which consists in inserting the light-proof covers with the layer-carriers into an exposing chamber in such a manner that the ends of the light-proof cover extend on opposite sides of the exposing chamber through light-proof slots; the slots themselves forming stop or abutment members outside the area of the layer-carrier inserted into the exposing chamber, and pulling hereafter the cover or elements of the cover so that same leave the exposing chamber, whereas the layer-carrier is retained inside through the action of the stop member or members. 2. An exposing case for carrying out the method described in Claim 1, having slots on two opposite ends, allowing the ends of the layer-carrier envelope to pass, one or each wall of one or both slots

being provided with an abutment-member for retaining the layer-carrier. 3. An exposing case, according to Claim 2, wherein one of the slot-walls of one or both slots is formed by a bar which projects from the supporting-surface of the layer-carrier case, and which is enclosed on one or both sides by counter-bars on the opposite slot-wall, for the purpose of providing a sinuous path for the envelope which is removable from the case, which path the layer-carrier cannot traverse. 4. An exposing case, according to Claims 2 and 3, in which the counter-bars for the bar projecting from the supporting-surface of the layer-carrier case are provided on a cover which is removably located on the exposing case. 5. As an article of manufacture and commerce a cut film in a light-proof envelope having an enlargement or thickening at one end for the purpose of holding back the film in the exposure case for use substantially as described. Optische Anstalt, C. P. Goerz, Aktiengesellschaft, Friedman, Berlin.

**CINEMATOGRAPH APPARATUS.**—No. 7,043, 1906. This invention relates to improvements in cinematographic apparatus by means of which prints may be rapidly rotated before the eyes. The claims are for: 1. Cinematographic apparatus comprising in combination with a lens or lenses adjustable on a frame or support, a rotary axle adapted to be mounted in said frame or support, and a plurality of blocks of cinematographic pictures

tangentially fixed to a support adapted to be rotated by said axle. 2. In cinematographic apparatus as described in Claim 1, the construction wherein stereoscopic lenses and stereoscopic cinematographic pictures are used. 3. Cinematographic apparatus substantially as described with reference to the annexed drawing. Ernest Reginald Law, 1, Rue Michel Roset, Geneva.

#### CATALOGUES AND TRADE NOTICES.

Jonathan Fallowfield, of 146, Charing Cross Road, has just issued a supplementary list of novelties and useful sundries, which includes many little things which should appeal to many of our readers.

J. J. Griffin and Sons, Limited, of Kingsway, have for some time been well known for their developing and toning and other chemicals in packets, cartons, and tins, and, in order to make these more widely known, they are now supplying sample sets at nearly half the usual price. As only a limited number of such sets are being issued it is necessary that immediate application should be made.

"Notes on the Use of the Wellington Specialties" is the title of a very readable and well-illustrated book of 87 pages which has just been issued by Messrs. Wellington and Ward, of Elstree. There is good, sound instruction in it, and many a useful tip for general

work may be learnt from a careful perusal of its pages. From the same firm we have also received a compact price list, which is extremely convenient for reference.

To-day Mr. J. C. Stevens, the well-known auctioneer, includes in his weekly sale some very good pieces of apparatus, the price of an amateur, which are well worth attention. They include a fine 12 by 10 parallel bellows camera, by Beck; a 7½ by 5 W. Premier with six slides; a No. 3 Dallmeyer Bergheim lens; a Dallmeyer 3 B lens; a Ross quarter-plate twin lens camera; Goerz lenses; a stereo Weno, besides two Dallmeyer rectilinear and two Beck's rectilinears and a tourist telescope by Baker.

## Commercial & Legal Intelligence

**CURIOUS BICYCLE STORY.**—Henry James Cray, 30, a photographer of 180, Markhouse Road, Walthamstow, was charged with stealing a bicycle. Last week Mr. Henry Brown, a laundryman, of B. Hurst Hill, went to the Working Men's Club, Woodford Green, and left his bicycle outside. He missed it half an hour later, and a prisoner was found in possession of it a quarter of a mile away. He was trying to mount it, but could not, and when told he would be charged with stealing it he offered all the money he had to be allowed to go. When charged, he said a man had asked him to mind it. The prisoner told a long story about being the worse for liquor and going about with a man he did not know. Some of the men quarrelled with his friend about a woman, and he (prisoner) went away. When he was rejoined by his friend the latter had a bicycle and when a woman came up and quarrelled he was given the bicycle to mind. Getting frightened, he went away, and when he was seized for stealing the bicycle he thought those who seized him were those who had quarrelled with his friend. He denied the theft, and was committed for trial, bail being allowed.

**PHOTOGRAPHY ON BRIGHTON PIER.**—De Joriette Plummer claims damages for breach of agreement against the Brighton Palace Pier Company. The case for the plaintiff was that, having discovered a process of rapid photography, he entered into an agreement, under which he worked a business on the pier on sharing terms. First, all work expenses were to be paid out of the gross receipts, and of the profits 40 per cent. were to go to the plaintiff and 60 per cent. to the Pier Company. In something under a year plaintiff's share came to more than £200. As it was obvious the business could be increased, plaintiff patented his process, and then entered into another agreement for three years, under which £60 was deducted for rent—the sum was increased when an additional room was found him on the pier—and the profits were to be divided equally. In this agreement was a clause that plaintiff should devote his whole time to the business on the pier. Plaintiff said that when he pointed this out, the secretary replied, "That doesn't matter, our company do not want you to be here all the time." It was known to the secretary, he said, that he had other businesses in Brussels, Croydon, Kensington, and Southsea. One gathered that for a time plaintiff carried on a business in the Western Road, Brighton, in connection with the Pier Company. Difficulties arose in 1904 between him and the new secretary of the company, and ultimately he had notice to quit the premises on the pier. Until he was given notice to give up his shops, he said he received no complaint that he was not attending to the business. His other businesses were under managers, and at the time he was under the Brighton Palace Pier agreement he had to give but little time and attention to them. Since he left the pier he had opened businesses at Eastbourne, Birmingham, Bournemouth, and three in London. The defence was that under the agreement plaintiff was the company manager of the photographic business on the pier. He was a shrewd business man, and contracted to give his whole time to the business, and also to carry it on to the satisfaction of the company. He had made suggestions as to a new agreement, but they came to nothing, and then, counsel said, the company found that he was carrying on eight or nine other businesses in different parts of the country, and was away from the pier more than half his time. Before he was dismissed he had locked the place up (in November) and taken the key with him. Now, after waiting a year, he claims £300 damages. If improperly dismissed, he could only claim what

was out of pocket; if he had established other business—better businesses—he had sustained no damage. Mr. Nomico, former secretary to the Pier Company, said he had no knowledge that plaintiff was carrying on any other businesses than that on the pier. C. T. Ford, the present manager, said the same, and he and other witnesses spoke of Mr. Plummer's frequent absences. Mr. Peake, a director of the company, said the company found all the capital, and took all the risk of the business in the Western Road, and the profits were shared. It was late on Saturday afternoon when a special jury who tried the case found a verdict for the plaintiff. No sufficient evidence had been submitted to the jury for them to assess the amount of the damages sustained, this question is to go to an official referee. Upon his decision depends also, to some extent, the question of costs.

CARL HEINRICH WILLY PUTZ (trading as H. W. Puetz), Photographic Chemical Merchant, 6, Savage Gardens, E.C.—The order of adjudication in this case was made in April last, and on July 13 the case came before Mr. Reginald Brougham, sitting at the London Bankruptcy Court, in connection with an application by the bankrupt for his order of discharge. Mr. Egerton S. Grey appeared as Official Receiver, and Mr. Oscar Osborn (Osborn and Osborn) on behalf of the bankrupt, the petitioning creditor, Emmanuel Bridault, merchant, of Paris, being represented. The liabilities, as estimated by the bankrupt, amounted to £1,069 1s. 10d., but proof of debt was only £167 8s. has so far been lodged, and the probable claims not yet proved amount to £31 11s. 1d. The assets, which were valued at £81 5s., have realised only £25. The difference between the actual value and the bankrupt's estimate of his assets is accounted for mainly by the fact that £40 of the available assets were subject to a claim for distrainable rent. It is not expected that any dividend will be paid to creditors. Upon the case being called, Mr. Osborn stated that he wished to give formal notice to the Official Receiver to dispute certain of the allegations made in his report. He had given a general notice, which was insufficient, but he had only recently had an opportunity of inspecting the report, which the bankrupt did not consider was quite correct in all its statements. In the circumstances, an adjournment of the application was applied for by his client. The representative of the petitioning creditors said that he had given notice to dispute the application on grounds other than those contained in the Official Receiver's report. He was perfectly ready to proceed with the case. His Honour ordered an adjournment of the application for a fortnight, but said that the bankrupt must pay the costs consequently incurred.

VAN DER WEYDE, Henry, Photographer, 182, Regent Street, W.—The order of adjudication in this case was made in March, 1902, and the bankrupt applied on July 10, to Mr. Registrar Linklater, sitting at the London Bankruptcy Court, for his order of discharge. It was reported by Mr. Egerton S. Grey, who appeared as Official Receiver, that the trustee had admitted proofs of debt amounting to £9,582 15s. 7d. in respect of liabilities estimated by the bankrupt at £12,627 13s. 9d. The assets, which were estimated to produce £2s. 4d. only, realised £163 14s. 4d., and a first and final dividend of 13d. in the £ had been paid. The difference between the actual value of the assets and the bankrupt's estimate was accounted for partly by the payment over to the trustee by the landlords of the bankrupt's business premises of the sum of £65 recovered by him in excess of six months' rent; partly to the holder of an assignment of book debts, amounting to £67 8s. 6d., surrendering her claim; and partly to realisation of copyright, etc., £65. The bankrupt was an American subject. In 1877, being in debt to the extent of £200, and having no assets other than patent rights, he began business as a photographer at 182, Regent Street, W. To meet his need for capital he borrowed £3,000 of one Dallas, but subsequently became financially embarrassed, and, in 1879, he called together his creditors, and paid them a composition of 2s. 6d. in the £ on liabilities of between £3,000 and £4,000. To Mr. Dallas he assigned a patent in satisfaction of his claim. His difficulties on that occasion arose through his devoting much time and attention to his inventions to the detriment of his photographic business. After that failure he borrowed £4,000 from a Captain Austen at 10 per cent. interest, and continued to trade at 182, Regent Street. He also continued to work at his inventions, leaving his business to a

manager, by whom considerable losses were incurred. In January, 1882, he (debtor) borrowed of one Taylor £1,500, which was paid to Captain Austen on account of his claim, and seven years later a Mrs. Hext lent him £2,000, which was paid to the Captain in settlement of his debt. In 1892 Mrs. Taylor died, and her executors accepted £350 in full discharge of their claim, but his debt to Mrs. Hext was still due. The bankrupt was continually in difficulties, and shortly before the date of the receiving order owed over six years' rent (£3,088) to his landlords, who then distrained. In 1894 he promoted a company, but, owing to an injunction being obtained against it on account of the noise made at its factory, it was wound up. Since his bankruptcy he had been chiefly supported by friends, who had advanced him £1,800 to exploit other inventions, which had, however, not yet proved successful, and he had delayed applying for his discharge in the hope of being able to realise such inventions and pay a substantial sum to his creditors. The bankrupt attributed his failure to loss on trading and his inability to realise on his inventions. His loss on trading between 1898 and 1901 amounted to £2,034, and his drawings for household and personal expenditure during the same period to £2,401. He had been aware of his insolvency since December, 1897, when his balance-sheet showed a deficiency of £1,089. Of the unsecured indebtedness £4,000 or thereabouts had been incurred since that date, and his deficiency, as shown by results, had increased to £9,419. The bankrupt's occupation was originally that of a portrait painter. As already stated, he subsequently became a photographer, and his business proved very successful. He devoted, however, such an amount of time and attention to experimenting on, or exploiting, various inventions that his business suffered, and, in 1879, he was compelled to make the arrangement with his creditors. Nevertheless, he continued his experiments in various directions, and had taken out, or applied for, in all some fifty-six patents, none of which had proved financially successful, and which had involved him in very heavy losses. As offences, the Official Receiver reported that the bankrupt's assets were not of a value equal to 10s. in the £; that he had continued to trade after knowing himself to be insolvent; that he had contributed to his bankruptcy by rash and hazardous speculations and culpable neglect of his business affairs; and that he had on a previous occasion made an arrangement with his creditors. Counsel, appearing on behalf of the bankrupt, asked that the discharge might be granted subject to a judgment being entered up against his client for a sum sufficient to pay the creditors a composition of 5s. in the £. He was prepared to pay £500 down in a very short time, and the balance of the money necessary to pay the composition would be provided at a later date. The Registrar remarked that the proposal was rather vague, as there was no security for the payment of the composition suggested, and, in the circumstances, he thought that the bankrupt would be wise to take an adjournment of the proceedings with a view to his putting somewhat more of substance in his offer than there was before the Court at the present moment. The application was accordingly adjourned for a month.

A SPECIAL exhibition of photographs taken by Captain Godfrey Faussett, R.N., Equerry to H.R.H. the Prince of Wales, is now open at 59, Brompton Road. These exhibits are particularly interesting, as they were taken, of course, from the same point of view as seen by the Royal party. Possibly the most interesting are those of wild elephant capturing and a Burmese dancing girl. Many prints also show the game that had fallen to His Royal Highness' gun. With the above are also a series of enlargements from negatives taken by Her Majesty the Queen, and a whole series of enlargements from the negatives of many distinguished amateurs. The exhibition is well worth seeing.

THE International Printing, Stationery, and Allied Trades Exhibition, which will continue at the Agricultural Hall, Islington, N., appeals in many of its features to photographers, not only as regards three-colour printing, but also in the show of picture post-cards.

MR. R. H. BEAVEN, who has been for many years with Messrs. G. W. Wilson and Co., of Aberdeen, has now been appointed the northern representative of Mr. C. Corn, of Upper Street, Islington, and will shortly start on his journeys to Scotland and the North of England.

## News and Notes.

**THE Bristol Photographic Club.**—This club has arranged an unusual form of competition for members in connection with its autumn exhibition. The judges will be asked to select the four best works by members and to place them in their order of merit. This list will be put into a sealed envelope and not opened until the fifth day of the exhibition. During the first four days all members will have the right to vote upon the pictures. The member's picture placed first by the judges will receive a special silver plaque; the member whose picture is voted as best by the members will receive any picture in the exhibition he may choose, valued at a guinea; while the member whose voting list agrees most nearly with that of the judges will also get a picture of same value. This competition should cause every member to take a keen critical interest in the exhibits, and stimulate their study of what constitutes a "picture."

At the last meeting of the Physical Society Mr. T. A. Vaughton pointed out that it has been frequently noted by several observers that some metals, such as aluminium, cadmium, zinc, magnesium, etc., although not radio-active in the ordinary sense of the word, yet have the power of affecting a photographic plate. The electric spark has a remarkable influence on this "activity," in some cases causing an increase, and in others apparently diminishing it. The alteration is not merely momentary, but remains for months. It is, however, quite superficial, and may be removed by slightly rubbing the surface with emery-paper. In the case of aluminium sparked with gold, the direction of the current does not make much difference in the activity of the sparked plate, but in the case of other couples the difference is very marked. For example, if a cadmium strip is sparked with antimony, the cadmium being connected with the positive terminal, the cadmium becomes very active photographically, not only on the spot sparked, but all over its surface. If, however, the cadmium is connected with the negative terminal and sparked with a positive terminal of antimony, the cadmium remains very slightly more active than if not sparked at all.

**LONDON and Provincial Photographic Association.**—September 6, 1906, has been fixed as the last day for receiving for consideration copies of papers read before other societies for adjudgment in the "Henderson Award." This award, which is given yearly, is one of the value of £5, and it may be in cash, a gold medal, or a silver or bronze medal and cash, or apparatus as selected by the recipient of the award. It is made to the author of the best paper on a photo-chemical or kindred subject, and the Association will be glad to receive copies of such papers for consideration through its secretary, Mr. Herbert C. Rapson, 13, Shaftesbury Road, Hornsey Rise, N.

"**SUMMER HOLIDAYS**" is the title of an edition de luxe of the G.E.R. Company's handbook to the seaside resorts and broadland served by this company, and it is thoroughly well illustrated, not only with reproductions in line and half-tone, but has also some excellent three-colour full-page reproductions of water-colour drawings.

On Saturday, 7th inst., the office and warehouse staffs of Houghtons, Ltd., took their annual outing up the river, travelling from Hampton Court to Runnymede by "La Burgoyne." Lunch and tea were served on board in the saloon of the boat, and parties of fifty sat down at a time, one or other of the directors acting as chairman for each party. At Runnymede the boat stopped for an hour, and afforded an opportunity for a ramble in the fields. The crowds of boats returning from Henley rather hindered the passage of the locks on the homeward journey, and Hampton Court was not reached till nearly ten o'clock in the evening. Nearly 200 members of the staff were on board.

**Hove Camera Club.**—An exhibition of prints representing Canadian work has been held at the headquarters of this society. The collection was brought together by H. Mortimer Lamb, and as well as pictures by himself, included work by Sidney Carter, A. S. Goss, J. A. Hodgkin, and Rex Stovel, all names of repute in Canada. The exhibits were mainly portrait studies, Canadian landscape not lending itself to photographic rendering, although "The Avenue," by J. A. Hodgkin, and Mr. Mortimer Lamb's well-known prints, "At

Last" and "A Forest Portal" were very striking. The portrait was of a very high order, largely "Salonesque" in treatment, particularly noticed a portrait of a child by A. S. Goss, a character study in light tones, and a print by Sydney Carter in gum intints.

"This is a free country, and the rights of the press must be held." With this declaration a magistrate at Oyster Bay Island, fined James Swan, in command of the secret service accompanying President Roosevelt, £2 for a technical assault on Clarence Legendre, a newspaper photographer. On the day President arrived at Oyster Bay to commence his much-needed summer holidays Legendre was waiting outside the station with a crowd of other people. Mrs. Roosevelt, he said, gave permission to photograph her husband, and for that purpose placed his camera in the middle of the road, with the intention of taking a snapshot of the President as he entered his carriage drive to his country home at Sagamore Hill. The same sort of thing had been done for years all over the country, sometimes without consent even of the wife of the party chiefly concerned. Swan, however, thought that Legendre came too near the sacred presence, ordered him back, finally pushing him into the crowd on the pavement. Such interference with the rights of the pictorial press understood here was bound to be resented. Swan apologised, too late. He paid the £2 fine in preference to going to gaol for days, and now he will be sued for £50 damages in a civil suit.

We have received the following further contributions to the Mawdsley Fund: G. W. Green, 10s.; C. R. Pearce, 4s.

"From the Art Studio of Ford, producer of portraits, 'Sunbeam Studio, Egremont,' is the title of an excellently got-up booklet, daintily printed and illustrated with some good half-tones. Some very useful hints to sitters are given, and the whole is well calculated to draw attention and business.

## Correspondence.

- Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- We do not undertake responsibility for the opinions expressed by our correspondents.

### PHOTO COPY PROCESS.

To the Editors.

Gentlemen,—In Mr. Shawcross' reply in your issue of July 6 I am glad he admits no claim to the introduction of the ferro-gallic process, although your issue of the 22nd June distinctly states it was due to him. He further says "Colas" published form "professed" to give these results. Why, his own, as described in his patent (8771) is an exact copy of "Colas" original, with quantities of the ingredients slightly altered. The only possible claim he can make is the using of the same developer in different form.

I adhere to my statements that I saw manufactured, both in the Continent and in the States, a water bath gallic paper long previously to his patent. It was certainly arrived at by a different plan, and one which at the present day is still considered much superior, viz., by giving the paper a second liquid coating of solution and developer, and not by rubbing in the gallic acid in a dry form by mechanical means—a very crude and uncertain method. The above plan was in no way an infringement of Mr. Shawcross' patent, nor one he could lay any claim to. It worked as a trade secret, and was not to my knowledge patented.

Is it not possible that the northern firms he so bitterly complained of may have adopted some such plan, and are perfectly entitled to claim the process as their own?

Marions made "Gallic Paper" previous to his patent, and in reference to them will confirm my statement. I did not say "water bath paper."

**Sepia Paper.**—Arndt and Troost may have only patented this paper in Germany in 1894, but it was put on the market by them there years previous to that date. It is a peculiar incident that Mr. Shawcross patented his in France and England, but carefully avoided Germany. Also when Arndt and Troost patented it in England, it was unopposed by him, or, if so, unsuccessfully. At a later period this firm were applying for injunctions, and stopping

of this paper all over the country. Why did he not step and raise the question then? Were they able to show a claim? As far as I am concerned this discussion is now closed.—Yours truly,  
MARGRAND.

#### AN APPEAL FOR HELP. To the Editors.

Gentlemen,—In your issue of to-day I saw an appeal from Mr. Milton Christian for help for Mrs. Sargent. I fully agree with in every way that hers is a deserving case. Last summer she and on me in Hull in distressed circumstances, since when she tramped up to London in search of work. Last Saturday she and on me here, on her way to Grimsby, where she expected to do a little work to tide her over for a time.

Should any subscription list be open or opened for this poor I shall be only too glad to subscribe my mite.—Faithfully  
MIGNON.

We need hardly say that we shall be pleased to assist by giving any subscriptions.—Eds., B.J.P.]

#### THE ARCHITECTURAL POSTAL CLUB. To the Editors.

Gentlemen,—Will you kindly allow me to draw attention to the fact that there are vacancies for two or three workers in the Architectural Postal Photographic Club. The club was started in 1904, for the study of architectural photography in its many branches, and has had a very successful career. The annual subscription is 1s. 6d.

A lantern slide section will be formed, to start next season. A good architectural slide maker will be gladly welcomed, so that the sets may start by October next.

All particulars may be obtained from me.

Bedford Square, Loughborough. J. E. UNDERWOOD, Hon. Sec.,

#### THE P.P.A. AND ASSISTANTS' CERTIFICATES. To the Editors.

Gentlemen,—Everything must have a beginning. The P.P.A. is not perfect—probably nobody has said or thought it was—surely it has begun in the right way. Even in the early days the Fellowship of the Royal Photographic Society it was granted me and all; but now it is by no means an easy title to obtain.

Thus it must be with the P.P.A.; one and all must be admitted even a few of the backyard men—till its gets sufficiently strong to stand alone, and lay down the law to photographers generally, and to the much-despised ones.

“Disgusted Assistant” hopes to form a Photographic Assistants’ Trade Union, he is almost doomed to disappointment. Let me look back through the files of your pages for the last ten years, even the almanacks, and see the numerous attempts that have been made at this sort of thing, and the utter failures they have of them been.

One has an uncomfortable feeling that in the letters of your correspondent one has a good example of the old saying: “Out of the fulness of the heart the mouth speaketh,” and that if he is being paid 4½d. an hour by these “amateur professionals,” is all he is worth.

Abuse of your opponent is no good, and ink and mud slinging helps case either, whether weak or strong. In my opinion, your correspondent has gone the right way to alienate the sympathy of many sides that of, yours faithfully, ANOTHER DISGUSTED ASSISTANT.

#### PROPOSED SOCIETY FOR COLOUR PHOTOGRAPHERS. To the Editors.

Gentlemen,—The letter in your last issue by Mr. Comley, is not no doubt satisfactory from some points of view, is in others distinctly unsatisfactory. For instance, I am a beginner in colour work, and should like, therefore, to know what advantage it will be to me to see the ambitious, but unsatisfactory results by other beginners, and how am I to learn from them?

The suggestion that skilled workers will aid seems to me to be a little visionary, and as, no doubt, many would propose to work commercially, is there not a chance of some little jealousy being excited, for I have not found that my brother professionals as a rule are prone to help me to compete with them?—Yours faithfully,  
A COUNTRY PROFESSIONAL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.

## Answers to Correspondents.

\*. All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C.” Inattention to this ensures delay.

\*. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\*. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- A. L. Twist, High Street, Bulith Wells, Breconshire, South Wales. Photograph of H. P. Wardle, Esq., Master of the Hawkstone Otterhounds, Holding an Otter above his Head away from the Hounds, on the Wye at Bulith Wells.
- G. Hynd, High Street, King's Heath, near Birmingham. Two Photographs of the Rt. Hon. J. Chamberlain, Esq., M.P., at Highbury after his Birthday Celebrations, July 10.
- W. G. Honey, 102, Patrick Street, Cork. Three Photographs of their Excellencies the Lord Lieutenant of Ireland and the Countess of Aberdeen.
- R. Wilkinson, The Studio, Hornsea, Yorkshire. Photograph of Traction Engine and Wagons with Aldborough School Children returning from the Seaside.
- Mrs. E. Denison-Biuns, 44, Mersea Road, Colchester. Photograph of a Group of Old Soldiers.

COPYING.—I enclose some negatives of a deed which I have been asked to copy; it is on parchment, and the ink rather faded. My trouble is that I cannot get enough contrast between the parchment and the ink. Can you suggest any particular method of procedure likely to succeed?—RANWORTH.

Use a slow process or photomechanical plate, and do not give too long an exposure. Develop with hydroquinone, 8 grains; sodium sulphite, 30 grains; formaline, 10 minims; water, 1 oz. Continue development as long as there is no sign of deposit in

the letters, and then fix, wash well, and if the parchment is not dense enough intensify.

**PUBLIC RIGHTS AND PRIVATE FOOTPATHS.**—Am I at liberty to walk across a field by the public footpath and take a photograph of private property? If so, am I at liberty to copyright and sell the views? I was last week warned off such a place.—**TRESPASSER.**

The owner of land through which runs a public right of way has not the slightest power to prevent anyone from taking a photograph therefrom, for whatever proprietorial rights he may possess in the demesne he certainly has no rights in the view as a view, therefore you can do what you like with it. The question, of course, is complicated by the fact that the footpath, being public, is public as a highway only, and this must be used in a reasonable and usual mode. It would be a very nice point for the Courts to decide, but commonsense certainly says that, provided no obstruction was caused, the taking of a photograph cannot be said to be an unreasonable use of the footpath.

**T. A. BAKER.**—1. Certainly you must secure fresh copyright for the new picture. 2. You must have a new block made.

**BLACK SPOTS ON ENLARGEMENTS.**—I have some enlargements which show numerous black spots. How can they be removed without injury to the film?—**S. H. BREAM.**

The usual plan is to apply the following, with a very fine camel's-hair pencil:—Potassium iodide, 30 grains; iodine, 20 grains; potassium cyanide, 20 grains; water,  $\frac{3}{4}$  oz.; glycerine,  $\frac{1}{4}$  oz. Dissolve in the above order, and as soon as the spots disappear, blot the solution off with clean blotting paper and wash well.

**BACKGROUNDS.**—What is the usual material for making backgrounds, I mean the cloth?—**T. WHITE.**

The usual material is unbleached sheeting, which may be obtained up to about 8ft. in width. This should be well damped, strained on a frame, and then given a thick coating of warm size before painting.

**FRENCH PASTELS.**—Can you kindly tell me where I can obtain French pastels for working up bromide enlargements?—**M. BLACK.**

Reeves and Sons, artists' colourmen, Moorgate Street, E.C.

**NEGATIVE MARKINGS.**—I enclose some negatives, and shall be glad if you will explain what has happened, and if there is any method of removing the marks. The negatives were developed with hydroquinone and immersed in a fixing bath containing alum.—**OPERATOR.**

This is the characteristic marking which is always obtained when a film containing an alkali is immersed in a solution of alum or one containing alum, the alumina or hydrate of alumina is precipitated in the film in a gelatinous condition, and, so far as we are aware, there is no method of removing them. When an alum bath is used after development or an alum fixing bath, it is essential to wash well after fixing.

**LENSES.**—I have just bought an expensive anastigmat, but I find on testing it that the definition at the sides of the plate is not so satisfactory as with my old R.R. Is this as it should be, and what is the fault?—**OPTIC.**

The fault lies in the test, a street scene, with the lens pointing straight down the centre of the roadway is no test for a lens, as the houses on each side would be obviously nearer the lens than the extreme distance in the centre, and if this was focussed on the roundness of field of the old R.R. would be an actual advantage, as this would probably compensate for the nearness of the object. If you want to roughly test your lenses take the flat straight face of a house or pin up a large newspaper and make comparative exposures with full apertures. Then you will be better able to judge.

**T. BROS.**—He died on May 25, 1905. See the "B.J." June 2, 1905, p. 435.

**F. V.**—Certainly not.

**CHROMO.**—We have handed your letter on to one who may help you and who will write you by post.

**COPYRIGHT.**—Your opinion and advice on the following matter greatly oblige. In June, 1903, a shopkeeper paid me for permission to reproduce one of my copyright photographs, others, in a small book of views. Since that time the said shopkeeper has gone bankrupt. Now I find that the printer's book is issuing the same kind of book to local shopkeepers still containing my view. I do not wish or expect to gain anything from this, which I consider an infringement, but I to know how the law stands in the matter. I have looked the "B.J.P." for several years back, but I cannot find a case. What I wish to know is: 1. Does the bankruptcy of my agreement with the shopkeeper? If so, in what? 2. Is the printer within his rights in sending the books to shopkeepers to sell without my permission? 3. Can I stop publication and sale of any more books containing my view? Can I proceed against the shopkeepers that are selling the containing my view? 5. Can I demand the block to be given me or have it destroyed? I have been told by one shopkeeper that I can do what I like, he will still keep on selling them. I have written to the publishers, and I enclose a copy of the letter, also a copy of my agreement with the shopkeeper. It is simply a case of who and what is right.—**D. G.**

(Copy of Agreement).

Agreement between A on the one part and B, both of the part of ——. That B be allowed to print ten thousand copies of photographs of —, registered No. 000000, or instruct be printed same number for the consideration of One Guinea (£1 ls.), in one style—viz., for retail at one penny each in Blankshire Book. Signed, etc.

(Copy of Letter from Publishers).

Dear Sir,—In reply to your letter with regard to view Blankshire Book, this is part of a book we printed some years since. We note your name is acknowledged on the view in question, and you gave permission to Mr. B to use the view and most of the edition was done and taken by him, and had permission through Mr. B to use it at the time.—Yours faithfully,

C. AND CO., LTD.  
1. B, having become bankrupt, his right of reproduction to 10,000 copies might be an asset of the estate and might be sold to a purchaser. 2. If the printer bought the rights in the Blankshire Book then presumably he would have the right to continue to print a reproduction of your photograph up to 10,000 copies. 3. Provided that a new edition in excess of the above stated number has been published you certainly have strong right of action. 4. Yes, if the 10,000 is exceeded. 5. You can demand destruction or delivery of the block, a return of copies sold above the 10,000, and claim for damages. This is an important case, and as the publishers are a big firm and probably prepared to put up a good fight or bluff it through their solicitor, we should strongly advise you to place it at once in the hands of a solicitor, or apply to the Copyright Union, 23, Soho Square, W.C. In any case B had no right to give them permission to use it, except for his own book.

**A. K.**—1. Dawbarn and Ward, 6, Farringdon Avenue, E.C., supply. 2. Use a slow plate and expose to artificial light contact with the negative.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

# Economy in Postcard Printing.

The "Hana" Bromide Printing Machine is an ideal instrument for the photographer who wants to make 50 or more prints from one negative.

This machine is designed specially for printing on cut sheets and postcards with the utmost possible speed, accuracy, and ease. It is substantially constructed, and well-finished, but without superfluous embellishments, and is meant for continual and practical use.

The negative is firmly held in the machine by a grip-frame which has flexible adjustment, and is instantly gripped or released by simply moving an arm lever.

The paper or card is placed against three points, so that each succeeding sheet is in exactly the same position on the negative.

**Price complete,  
as illustrated,  
with "Kern" Incan-  
descent Burner,**

**£4.15.0**

Perfect contact is insured by a pivoted pressure back which distributes the pressure evenly and automatically by coiled springs which are provided with adjustment for more or less pressure as desired. It should be noted that direct foot pressure is not exerted against the negative, thus obviating any risk of breakage.

The light used in the machine for printing can also be used for developing on either or both sides of the machine; it is constant — *not turned on and off during printing*. The exposure is automatically effected by a shutter, there is no actinic light in the room during the changing of either the prints, negatives, or vignettes. The lamp has two ruby glasses, and full-sized yellow fabric panels, one on each side, which give a good illumination all over the dark room.

Changing the paper is done with certainty by hand, both hands being free for this purpose only; one hand takes off the exposed sheet, and the other one places a fresh sheet on the negative down against the guide points.

All the working of the machine is done by treadle. When a fresh sheet of paper is placed on the negative, the heel is pressed down, and that one movement first closes the pressure back and then opens the shutter.

## HOUGHTONS LTD

Manufacturers of the "Hana" Bromide Printing Machine.

88/89, HIGH HOLBORN, LONDON, W.C., and at GLASGOW.

If you print Postcards, let us send you our Illustrated Book on the "Hana" Machine.

It comes free by return.

*It is the only really practical Bromide Printing Machine that has ever been put on the market at a reasonable price. It will work regularly and evenly without the slightest attention or waste of time. The results will be uniform and entirely superior to any ordinary hand printing machine.*

## SUMMARY.

A simple method of examining and drawing the plane projection of the three-dimensional image, as given on the ground glass of the camera. (P. 583.)

The possibilities of cinematography in colours, with the suggestion of an imbibition process will give each little picture complete colour. (P. 584.)

The recommendations of the Joint Committee of the Lords and Commons will, if carried into law, press hard on some photographers to now rely on Sunday trading. (P. 582.)

Picture postcards are suggested as a cheap and effective means for the study of posing and lighting by eminent workers. (P. 582.)

The analysis of a half-tone portrait with comparative illustrations and measurements of the dots in light and shadows. Standards suggested which may prove useful when harsh criticism is applied to results. (P. 585.)

The artistic value of glossy prints and a strong protest against the too frequent prevalence of matt surfaces and blurred masses devoid of any drawing. (P. 587.)

A summary of the present status of colour photography, a paper read at the Photographic Convention on July 13, at Southampton. (P. 588.)

Mr. H. J. Comley suggests that the Convention is a neutral ground, where all professional disagreements may be forgotten and personal fellowship be fostered. (P. 592.)

A deep green filter for dark room lamps, which is specially useful for red sensitive plates. (P. 592.)

A working formula for casein printing-out paper. (P. 593.)

A new three-colour camera, devised by Sir William Abney. (P. 595.)

The P.P.A. and Assistants' Certificates still claims attention. (P. 597.)

## EX CATHEDRA.

### A Practical Use for Three-colour Work.

Whilst many will not admit that the present position of three-colour photography is such that it can be profitably applied by the professional to every day portraiture, there are other fields in which it may be useful. For instance, there is lying in front of us now an excellent three-colour half-tone of a tapestry covered armchair, which has been issued by a furniture manufacturer with his price list. This was made from a set of three-colour stained films, which were merely securely bound together by one edge, that not only could the block-maker see the subject complete in all its colouring, but so that each individual positive became a guide to the fine etcher as to what was and was not wanted. This principle is obviously applicable to many cases when it would be utterly impossible, either from the size of the object or other circumstances to send it to be photographed. Considering how easy it is to make such positives and how easy to so adjust results as to obtain correct colour rendering there should be a fairly wide field open for this particular application of three-colour work.

\* \* \*

### Ozobrome and Three-colour Work.

It was but natural to connect the process of ozobrome with the production of three-colour carbon prints, and Mr. Manly has shown us some specimens by this process which are extremely effective, and one in particular the original of which we happen to know was very true to colour. It is obvious that by this process the production of three-colour prints will not only be considerably facilitated, but that it means a very great saving in time. One has merely to make as many sets of bromide prints from the three constituent negatives, as one wants colour prints, and they can all be treated at once. This should render the production of colour prints by professional photographers a much easier matter, and it will further enable the negative to be taken of a small size and then direct enlargements in colours can be obtained.

\* \* \*

### Dark Slide Shutters.

The notes which have recently appeared in our pages on this subject have been somewhat contradictory. That on page 542 referred to the experiments of Herr Beckers, whose conclusions were distinctly negative of any fogging or other deleterious action of aluminium. Now in "Die Photographische Industrie" an amateur returns to the charge and gives instances in which plates left in dark slides with aluminium shutters showed black patches and fog after only twenty hours. Now Herr Beckers states that since his previous note he has repeated his experiments with aluminium and left

plates in the slides for a whole week and has found no ill results. His suggestion is that when there is trouble it must be ascribed to radio-active impurities in the metal and not to the metal aluminium itself. Considering the large number of dark slides which are now issued in England with these metal shutters, we should have thought that we should have heard something before this had any pronounced trouble been met with.

\* \* \*

#### **Sunday Trading.**

Two or three times during the past few months reference has been made to proceedings that have been taken against photographers for following their business on the Sunday. The only proceedings, at the present time, that can be taken against those who do so is under the antiquated Act of Charles the Second, passed in the year 1677, and the greatest fine for its infringement is five shillings only. Some little while ago a Joint Committee of Lords and Commons was appointed to inquire into the question of Sunday trading, and it completed its labours last week. Here are some of the recommendations the Committee now make. One is that the general principle of the Act of 1677, in regard to Sunday trading, ought to be maintained, and that the penalties imposed by that Act, in consequence of the change in the value of money, are now inadequate for securing the end in view. Another is that the exigencies of modern life make it necessary to permit, in particular districts, the sale of certain articles for a part or the whole of Sunday; and that special regulations necessary for this purpose should be framed by local authorities, under proper supervision and confirmation by the central authority. Two recommendations of the Committee will be of interest to photographers who carry on business on Sunday, if they are permitted to do so should the recommendation be enforced by an Act of Parliament. They are these. First, that every shop assistant, and presumably photographic ones, should be secured by law one day's rest in seven, and that no such person should be subject to any penalty if he objects, on conscientious grounds, to Sunday employment. The second is, that any employer who places upon an assistant any obligation to work on Sunday as a condition of employment without provision for securing him one day's rest in seven should be subject to a penalty. This would secure to some employees a full day's rest that they do not now get. However, the recommendations of the Committee have not yet been embodied in a Bill, and there is no probability that they will be this session, nor in the next, but there is little question that the subject will come before Parliament in the near future. If photography is not one of the exigencies of modern life that it is necessary to permit, many photographers who do a large business on Sundays will suffer badly.

\* \* \*

#### **Duty Free Alcohol.**

It may be remembered that last year the late Government introduced a Bill, based upon the report of the Industrial Alcohol Committee, to permit duty free alcohol to be sold for purely industrial purposes, but owing to press of other matter nothing came of it. One day last week, late at night, the Financial Secretary to the Treasury moved the second reading of the Revenue Bill on the part of the Government. One of the main features of the Bill is to allow of the sale of alcohol free of duty when it is used for manufacturing purposes. In introducing it Mr. McKenna said that the case of the spirit free of duty would be about eighteenpence the gallon, but the duty itself is eleven shillings a gallon. At the present time alcohol is permitted to be sold free of

duty provided it contains ten per cent. of wood naphtha but the new Bill proposes to reduce this proportion to five per cent. This will tend to lower the price of methylated spirit, as the cost of the wood naphtha is considerably more than that of the alcohol itself. The reduction of the proportion of the naphtha will, also, render spirit more serviceable for some photographic purposes than it is at present. When the present methylated spirit is sold in less quantities than ten gallons, and then the purchaser must hold a license to purchase it, it must, in addition to the wood naphtha, contain a small proportion of petroleum spirit, which causes it to become opalescent when diluted with water. The Bill is not a controversial one and it passed its second reading the same night, at the Committee stage was set down for this week. The Bill, if it passes into law, as in all probability it will shortly, as it is a non-contentious one, will not be of the same benefit to photographers generally that it would have been when the collodion process was the only one employed. Still, collodion is largely used by process workers and for enlarged negatives, and the new Act will enable this material to be sold at a much lower price than it is possible at present with the duty-paid alcohol, which costs about three times the price of the ether it contains.

#### **The Study of Pictorial Postcards.**

Amongst the most attractive things shown in the windows of fancy stations at the present time is undoubtedly picture postcards—those of portraits of actresses and other celebrities perhaps receiving the largest share of attention. If one looks in the show-cases of the ordinary portrait photographers perhaps only a few doors off, one cannot help being impressed with the wide difference there usually is in the specimens there exhibited and those shown for sale by the stationers. Those shown by the former are doubtless his own work, while those displayed by the latter are, as a rule, by workers of high standing, both at home and abroad. In many provincial towns the difference is still more marked than it perhaps is in the metropolis. Is there any real reason why the difference should be so great? If photographers were to study these published portraits they could at once see how they could improve their work both as regards lighting and posing, yet they do not seem to appreciate the example set by really artistic portraits. There seems to be no real reason why this should be so for the examples are to be seen almost everywhere, and what is more, they may be purchased for about a penny or twopence each for study at leisure at home. Still, the opportunity does not appear to be largely availed of—or at least is not greatly profited by, judging by the specimens one sees in the majority of middle-class photographers' show-cases. Some may say I cannot get such lighting in my studio: that is a fallacy; any kind of lighting may be obtained in any form of studio if the operator has the ability to apply it. Others may say I do not get the same class of sitters to deal with, and the like. This may be correct to an extent, for it must be admitted that, generally, actresses do take, naturally, more graceful poses than is the case with ordinary everyday sitters, but the poses they take are not always the most suitable to photography, hence the artist, often, has to considerably modify them, and it is here his skill is shown. We should recommend country photographers whenever they visit London to make a point of taking back with them a few dozen of these portrait picture postcards, which are now to be had for as many shillings, and study them at home. If they were to make this rule they would quickly see the means of materially improving their own productions.

## THE PERSPECTIVE OF THE AERIAL IMAGE FORMED BY A LENS.

IN studying the formation of the image produced by a photographic lens, it should always be remembered that when the object is a solid, or three dimensional, the real image formed by the lens is also three dimensional. The flat, so-called "image" on the ground glass is then simply a plane projection of the three-dimensional image, and for many purposes it may very conveniently be looked upon as a shadow of the "solid image," cast by a source of light the size of the lens exit pupil. Many misconceptions have arisen through neglecting to consider the fact that the real image is three dimensional, and, very curiously, the perspective laws governing the form of this real image seem to have received little, if any, consideration.

Some little time ago we were led to inquire into this subject, and, somewhat to our surprise, we found that the formation of the aerial solid image produced by a lens is governed by extremely simple laws, far more simple than the optical laws that the student is usually compelled to observe when drawing the solid image.

The optical methods take much time and generally lead to a multiplicity of working lines that is very confusing. The perspective method is very rapid, and the resultant drawing of the image is almost free from working lines. Further, image points are determined by lines intersecting at fairly obtuse angles, while by the optical methods all such points are fixed by lines or rays intersecting at acute angles; so acute in many cases that the position of the point cannot be accurately determined without calculation.

The rules governing the perspective of the image are as follows:—

- 1.—Every line in the object and its corresponding image line will meet, if produced, in a point in the principal nodal plane of the lens.
- 2.—Parallel lines in the object are represented in the image by lines that converge on to a point (a vanishing point) in the principal focal plane of the lens.

It should be understood that in solid perspective (as in plane perspective) there is no way of fixing the position of a point other than that of representing two lines that intersect in the point. Hence to fix the image of a single object point we must draw two lines through the object point, and then on drawing the images of these two lines their intersection gives the image point. If the image of a point is determined by optical "rays," as many lines are involved, but we have little choice as to the position of the lines, whereas by perspective methods we can put the lines at any angles we please, and so secure obtuse intersections and great accuracy.

To illustrate the application of the two perspective laws given, we will consider the case of a simple horizontal square object A.B.C.D. of two dimensions only (see figure). If this object is a little below the axis of the lens, L, all four corners of the square will be visible to the lens, and they will be represented in the aerial image by the points a, b, c, d. The diagram represents all the various points in plan only. The line PnP is the trace of the principal nodal plane of the lens L passing through the node n, and the line pFp is that of the principal focal plane passing through the principal focus F. To illustrate rule 1, it may be noticed that the object line AD and the image line ad meet, when produced, in the principal nodal plane at H, while under rule 2 the lines ad and bc, which represent the parallel object lines AD and BC, meet in a vanishing point in the principal focal plane at VP2. Rule 1 is also illustrated at the points E, G, and K, while VP1 is a second vanishing point for the lines cd and ab.

It is obvious that the points E, G, H, and K are easily

fixed by producing the object lines AB, CD, AD, and BC, until they cut the principal plane PnP, and that with the aid of these points and the vanishing points VP1 and VP2 it is easy to draw the image a, b, c, d. To determine the vanishing points we adopt an expedient common in all perspective methods. We assume the existence of an imaginary line that is parallel to the lines we wish to represent, but leads directly to the vanishing point. In this case, to find VP2 we assume a line MN parallel to AD and BC and passing through the node N of the lens. Under the laws of Optics the image of such a line must be in the same straight line, therefore if we produce this line to cut pFp in VP2 we have (under law 2) the vanishing point for the images of all lines parallel to MN, and therefore the vanishing point for ad and bc.

The diagram being an explanatory one contains more lines than are absolutely necessary. The dotted lines need not be drawn, for the only lines actually required are the principal nodal plane, PnP, and the principal focal plane, pFp. Having drawn these lines we lay a parallel ruler on BC, and where its edge cuts PNP we tick off the point K. We shift the ruler to AD and similarly tick off the point H. Then, keeping the ruler parallel to its former position, we place it with its edge on the nodal point N and tick off VP2. If next we lay a straight edge through

K and VP2 we can rule the line cb in the proper position, and of approximately the right length, and by shifting the edge to H and VP2 we can draw ad. On repeating the process on the other side of the lens we obtain the points E, G, and VP1, and through these points we rule the lines ba and cd, and so determine all four points a, b, c, d, this result being quite accurate and also clear and free from working lines. If an attempt is made to draw this image by ordinary optical methods it will be found that the points b and d cannot be determined with any approach to accuracy on account of the very acute intersections involved, while c and a will probably be in error. The positions will have to be calculated if optical methods are employed, and accuracy is to be ensured.

It should be observed that under rule 2 the principal focus is the vanishing point for all image lines that represent object lines parallel to the principal axis of the lens. Or, in the language of perspective, the principal focus is the "point of sight" in the system of lenticular solid perspective. This is a fact that is not generally known, but it is, as we have often found, a most useful fact to remember when studying optical problems that are not immediately concerned with perspective. The diagram given is a plan only, but the same construction will apply to a vertical section, and by combining a vertical section with a plan the complete construction of a three-dimensional image can be examined and studied.

## CINEMATOGRAPHY IN COLOURS.

THE exhibition of cinematography in colours given at the Photographic Convention at Southampton may possibly direct further attention to this subject. Although the rendering of moving scenes by the cinematograph is now so perfect that one may easily be deluded into the belief that one sees the actual objects, there is not the slightest doubt that if to this representation we could add colour, illusion would be still more perfect, and, from a scientific point of view, the cinematograph would be still more valuable.

Five or six years ago results in colour were shown by means of the cinematograph, but lately we have heard but little on this head. There is, however, obviously a possibility of the attainment of this object, particularly in the face of the latest advances that have been made in the colour sensitising of negative emulsions. Here was the crux in the old days. We had then no satisfactory red sensitisers; but now, given a suitable mother emulsion, there is no insuperable difficulty to so sensitising this as to make it comparatively easy to obtain fully-exposed negatives behind the red filter.

Naturally a good deal depends upon the filter; but as with the new filter dyes there should be a possibility of obtaining a ratio of exposures of 6:6:6 respectively for the blue, green, and red filters, there should be no difficulty in obtaining correctly exposed negatives in correct colour gradation. It should be possible to obtain these ratios, but we are not prepared to say how these filters can be exactly prepared, because more experiments are required; but it may be pointed out that, with a fairly open filter, an error in absorption could be compensated by under-exposure.

Assuming, then, that we have rapid panchromatic emulsions and rapid filters, we are face to face with the problem of obtaining the colour record negatives. This problem can only be solved by careful consideration of the method by means of which we are to project the pictures. We do not mean the actual mechanical means, but whether we are to resort to triple projection—that is, the so-called additive system in which light is added to light, or whether we are to use superimposed stained films. Then, again, there is a possibility of utilising the well-known persistence of vision, and to superimpose on the retina the impressions of the three colours so rapidly that the result shall be normal colour.

If we adopt the system of triple projection it is obvious that we must take three negatives side by side in such a manner that the three positives can be projected to superimpose. This means, of course, three lenses side by side, and one then has to reckon with parallax, which, however, is hardly likely to be of much moment. The far more important fact, from the practical commercial point of view, is that one must use a negative, and also a positive film, which is at least three times the width of the ordinary film, and that the negative film, being exposed behind stationary filters, must receive the correct ratio of exposures. Possibly, also, there might be a mechanical difficulty in moving a celluloid film of the required width with sufficient regularity and without the danger of the celluloid tearing or breaking down under the strain.

Having obtained the negative, one would have to make positives by contact, and practically repeat the movements for obtaining the negative in projecting the positive in colours.

If we adopt the persistence of vision method, by means of which we should take a series of negatives through violet, green, and red filters, alternating and repeating in this order, it is obvious that one has the mechanical difficulty of alternation of the filters synchronously with the negative film. Precisely the same trouble will be met with in projection. To say that this is impossible would be dogmatic, but it is obvious that there must be an enormous loss of light and enormous increase

in the cost of the taking and projecting instruments. The question next arises as to whether it would be possible to obtain negatives of each colour record, and so combine afterwards into one film that they could be projected by cinematograph. This immediately resolves itself into the question of printing.

Supposing that we obtained simultaneously the three-colour record negatives on one or three films, because for this it would be perfectly immaterial as long as the films for all three records were synchronously. Is it possible to so utilise one of our present printing processes as to obtain on one film a series of pictures each of which shall be in itself a perfect colour picture? If thus each picture, being itself a colour record, could be projected in any existing cinematograph lantern.

At the first glance it is obvious that we must at once reject any process in which superposition of stained films is used, the exposing, printing, and staining up of, say, 150 ft. of a colour record and superimposing of the same would be a task in face of which the labours of Hercules would be child's play.

The question remains, then, as to whether we could use an imbibition process. Here seems to be a possible solution of the question, for in these processes we have not the superposition of three films, but merely the transference of details to one film, and it should be possible, though possibly not easy, to obtain accurate register of the matrix films, for this would mean merely accurate mechanical movement, accurate perforation, and pressure.

Slight irregularities in superposition would probably be absolutely unnoticeable on the screen; and, however idealistic the suggestion is, this is what we want—a length of cinematograph film, each picture in which shall be a record of the movement at the instant of exposure, and at the same time in itself a complete colour record.

Assuming that this last idea is feasible, then one can conceive of three separate lenses, three separate negative films, and three separate colour filters, and of these the only one moving being the film, then one might, by means of an imbibition process, obtain one film, each picture of which should be perfect colour. Or one might use the alternating colour filter and obtain an alternating colour record negative, and, using an imbibition process, transfer each colour record to the other picture; this, at least, means accurate superposition.

So far as we could gather, the results shown by Captain Lascelles Davidson and Mr. Friese Greene were obtained solely by the aid of two colour records side by side on a standard negative film, and positives from these were projected in an ordinary cinematograph; in front of the objective was a colour-box, by means of which the two positives were combined. The impression one gathered, though possibly wrong, was that these experimentalists use two colour records only—a blue, green, and an amber or orange. If so, correct colour cinematography on these lines is impossible. We have here applied to the lantern precisely the same principle which Gartner, of Berne, has utilised in his two-colour process; where real reds are ignored, and whilst this may be useful for pure landscape work, it can never be a true scientific record of colour by the aid of cinematography.

These few notes are advanced rather with the hope of suggesting further work and experiment; possibly also because we believe that soon we shall see the problem solved. This we believe, notwithstanding the dictum of a distinguished member of the Photographic Convention, who, after the exhibition of the ordinary coloured slides and the cinematograph pictures, said that he considered three-colour photography as somewhat of a farce with playing the overture to Wagner's "Niebelungen Ring" with three fingers on a piano.

## ANALYSIS OF A HALF-TONE PORTRAIT.

A Paper in "The Inland Printer," by whose courtesy the illustrations are given.

The original photograph from which both half-tones are productions is a soft brownish-black platinum print with considerable "surface texture" showing in the background, so that it is not an easy subject to reproduce.

The engraving (Fig. 1) is inserted alongside of Fig. 2, not for purposes of invidious comparison, but to show clearly what variation in treatment and interpretation has been given to each of the reproductions.

It is impossible to properly appreciate the actual closeness of adherence to a given requirement unless one makes comparisons in the light that one condition may throw on another. The engravings themselves are made the subject of comparison so that the various modifying influences that interpolate between the engraving and their finished prints may to a large degree cancel each other, because the same personal equation is impressed upon each specimen.

When one realises how much misunderstanding and undeserved blame of reliable workmen arises from a combination of circumstances in which no particular blame can attach to anyone in the matter of printing half-tones, it becomes an important matter to lay such a groundwork for comparisons, establish certain standards of attainment, etc., as shall make the lot of all craftsmen an easier one, because there will be little or no carping criticism, but there may be a great deal of wholesome analysis of efforts and results that will be productive of far-reaching results.

Photographs or wash-drawings having a deep black background with little gradation in the middle tones when used as copy for half-tone

plates may show up well in the engraver's proof. This is because the ink can be placed on the cut with a hand brayer, and the overlays made to bring out deep blacks, middle tones and "whites" with all the gradation, and sometimes even better gradation than was present in the original copy. After the ink is on the plate the prover can, and frequently does, manipulate the plate by wiping off colour here and there after the style of the worker in gravure, steel die or copperplate printing.

The prover's mind is concentrated on getting a nice proof, and rightly enough from one point of view, for he has not been awakened to the fact as a general thing that the cut will come for is to set the pace for the man to whom the cut will come for interpretation on the cylinder press. What can be done on the Washington hand press can only be approximated on the cylinder press. A half-tone cut will not print dead black in the heavy shadows if the half-tone dot is there. The letterpress may carry so much colour that the type looks sloppy, yet the half-tone cut is

grey and dead. If additional colour is carried in a mistaken effort to make the shadows print solidly the entire cut is "mushed."

The customer who has a job to be printed with illustrations, should, as far as practicable, have all the work done by one house. The printer should be careful to give the engraver advice regarding the character of the stock and ink to be used and also information of the effect sought to be obtained. The engraver will adapt his work to the paper and presswork. Too often, however, a mixture of old and new cuts from a variety of sources and with a variety of meshes are given the pressman, and it is a very difficult task to reconcile, in the same form, the treatment an open cut requires with the treatment required by a solid cut. A cut that is made open by the engraver may be proved up to look like almost solid by the prover, but the pressman will find it difficult to make this metamorphosis on long runs on the cylinder press without spoiling the job by destroying the balance between the engravings on the type matter.

This brings us to the point of making an analysis of the two specimens shown. In order that it may be the more readily understood and the one compared with the other the characteristics are given in Table A, which summarises the values.

The analysis has to do with the screen pitch, unit area, diameter and area of the black and white dots, and the percentage of black and white of four tonal values. The points of observation are noted in the table.

Fig. 1 has 145 lines per inch, a screen pitch of .0069 inch, and a unit area value of 476. (.0000476 sq. in.).

Fig. 2 has 150 lines per inch, a screen pitch of .00666 and a unit area of 443.5 (.00004435 sq. in.).

The margins of the white dots in the background of Fig. 1 are ragged to a large degree, thus throwing the dots and the printing areas surrounding them out of symmetry, which produces a "blotchy" appearance. This is probably caused by too vigorous etching or too much heat when baking the "enamel." Either one would cause ragged edges. On the other hand, a slight excess of heat would partially destroy the acid-resisting properties of the enamel and thus allow the acid to attack the copper underneath over the whole of the area, but as the plate shows no such action, it is assumed that the defect is due to the lack of adhesion between the enamel and the copper to prevent the flaking away of enamel particles in the acid immediately adjacent to the edges of the dots, thus leaving a ragged margin.

It will be noted from the table that the tonal value of Fig. 1 in the background is quite abnormal. This is apparent at a glance

FIG. 1.—145 lines per inch.

by comparison of one print with the other, but what the *specific value* of such aberration is cannot be told in this manner, by offhand visual inspection, hence the desirability of scientific analysis.

When attention is called to certain features, *definite* values should be ascribed to the same. Tonal value should be referred to as diameter or area of dot, or percentage of white. The latter would be preferable, as it is easy to make up a table showing such percentage values for various screens and diameters of dots, giving *unit areas* as well. Black percentages are easily found by simply subtracting the percentage of white from 100.

By doing things along these lines, process engraving will be placed on the proper scientific plane, and the day of uncertainty, when the sentiment of the skit on indefiniteness, "As long as a piece of string and as big as a lump of chalk," was the rule, will have passed into oblivion.

The differences of the two engravings are clearly pointed out in Table B, which is self-explanatory. The areas for both the black and white values are given in Table A so as to more clearly show wherefrom the percentages are derived.

Taking the white area of the first column as 458.3 and remembering that the unit area for Fig. 1 is 476, the proportion of *white* contained in unit area (which is *altogether*

white) is expressed as  $\frac{458.3}{476}$

and the amount of black, due to the smallest black dots, as  $\frac{17.7}{476}$  or 3.72 per cent.

In Table B, the background of Fig. 1 is shown to possess

FIG. 2.—150 lines per inch.

almost twice as much white as Fig. 2, and in the "white" Fig. 1 has approximately half the white value of Fig. 2. The brilliancy of Fig. 1 is to be very much below that of Fig. 2.

To properly consider value of either engraving from the basis of interpretation, it is absolutely necessary to know the tonal values of the original photograph. This should be given numerically for the quarter, half, and three-quarter tones.

Having such a record it comes easy to know from table giving the sizes of dots, areas, and percentages, whether the interpretation is a faithful one or is but an approximation.

A reproduction may be faithful enough as to recognisability but it may at the same time lack all the subtle charm of true tonal values that differentiate an approximation from a true copy.

If unit area is taken as 476 whole or pure white will be represented by this number; white by 357;  $\frac{1}{2}$  white by 238;  $\frac{1}{4}$  white by 119;  $\frac{1}{8}$  white by 59.5, and no white by dead black that covers all of a unit square or unit area.

The dot diameters for these areas work out correctly until the point of 25 per cent. of black (75 per cent. white) is reached. At or near this point the dividing space between two contiguous depression (white dots) is etched away, and the law of periodic acceleration comes into play to modify the etching rate and also

the interpretation. If unit area is taken and the diameter of a dot is calculated therefrom which shall have the same area, it will be found when four such dots are placed with their centres coincident with the corners of a square, whose sides are equal to the screen pitch, that there will remain an uncovered area in the

of the square, even though the dot and unit area is exactly the same. In order to cover this area the dot diameter must be increased so as to be the same as the diagonal pitch. The reason for this tonal aberration is found in the fact that dots of such area and diameter as to equal unit area, when their centres fall at the corners of a unit area square, have their circumferences overlap at the sides of the square.

These deductions are based on round white and black dots. The "four crescent" dots beyond the "three-quarter" whites are amenable to a separate law.

## THE ARTISTIC VALUE OF GLOSSY PRINTS.

IF we are to accept unquestioned a dogma often enunciated by our readers "we should have to acknowledge that a highly glazed paper from the artistic standpoint, absolutely unsuitable as a printing medium. But fortunately for the progress of photography unreasonable obedience to the voice of contemporary authority has never been characteristic of those who practise this delightful and instructive science. Doubtless, also, this laudable independence is in no small measure due to a general belief that freaks of fashion rather than the outcome of ascertained truth have largely shaped the orthodox with respect to what does and what does not constitute "art" the finished products of photographic work.

From somewhat extensive inquiries I have made amongst manufacturers and retailers I find that whilst the popular demand for sensitised papers carrying a high gloss shows no signs of diminishing, a slight but progressive increased sale of matt surface papers has been noted in recent years. On this question photographers are divided into two separate and opposite camps. On the one hand is a select body of enthusiasts, who claim to represent the high-water mark of artistic ideals and accomplished work, and who not only insist on the exclusive use of matt surface papers, but place all glazed printing media on that Index Expurgatorius which marks the limits of artistic salvation. On the other side, and this is a matter of common knowledge, there are vast numbers of equally enthusiastic "serious" workers, equally well-educated, and with equal opportunities of possessing or acquiring the artistic sense, who habitually employ glazed papers, or who do so whenever they consider these are more appropriate.

### The Condemnation of Gloss.

In passing, it may be noticed, as a curious circumstance, that while it is extremely rare to hear a single voice publicly raised in favour of glossy printing, the crusade against their employment is vigorously carried on whenever an opportunity can be made or found. Not only is this the case with respect to the lecturers at our photographic societies and the writers in our journals, but the editors of the latter are frequently forced to inform their correspondents that the judges and committees of our leading exhibitions will not even look at a photograph if it be finished with a highly glazed surface.

But now, for once, let us glance at the other side of the picture and endeavour to discover why it is that the much condemned glossy print still retains its popularity in spite of the number and nature of the attacks made upon it during the past few years.

### The Suggestion of Light.

Photography, as we all know, depends essentially upon the presence and action of light, and it is self-evident that a very large proportion of photographs depict, with more or less fidelity, sun-illuminated scenes with contrasts of light and shade strongly or moderately marked. Further, in probably the majority of cases, the shadows accentuate the high-lights rather than the converse. In other words, the features of paramount artistic and material interest are not only brought into prominence and made visible by means of light, but also bear the impress of this creative agency on their surface. All this is doubtless of the nature of a truism, but upon the proper interpretation of such truisms we must, I believe, look to settle the problem now under review.

In photographs of the foregoing description, that is where the presence of light is the predominant characteristic of the salient features of the scene portrayed, the use of a glossy printing medium is essential, because it is most appropriate, and is consequently most

artistic, inasmuch as it harmonises best with the nature of the subject and assists to rivet the attention on what is important. If, on the other hand, a matt paper were employed, as is invariably done in "art" photography, in order to subordinate or obliterate natural effects, then a very clumsy and roundabout course is taken, as a clear proof is thus afforded that a faulty selection of time or subject has been made. But, in any event the man who deliberately determines radically to alter the visible values of one of the most important factors composing a picture assumes a grave responsibility. Before so doing, he may well ask himself whether his intuitive sense of the beautiful, or his training, is such as to qualify him to modify features of great artistic import in the scene he proposes to reproduce. In the long ago it was said by one who was inspired by that rare genius which voices the meaning of things that "the course of nature is the art of God," and if this be true there can be little doubt that the number of photographers who are entitled to blot out or completely repaint one of nature's pictures is exceedingly small.

It requires but a small acquaintance with the many and marvellous glories displayed in a sun-bathed or sun-embellished scene, such, for example, as so often are open land and seascapes, to realise that much of their beauty would necessarily be marred or lost were they reproduced as sombre spiritless forms by the employment of matt surface printing.

Sunlight, especially when spread over large areas, graphically connotes life and the concomitants of life, but if we dim that light by lustreless printing we cast a pall over the scene that creates the impression we are in the presence of inanimate objects. The outward form may dimly be discerned, but the vitalising power of the soul within is gone.

### The Beauty of Detail.

Another (and a crowded) category of photographic reproductions is that in which detail, well or badly lighted, forms an important feature. Now, in the latest "school" which at present dominates "art" photography, and which is largely founded upon a misconception of the methods of the painter, all detail is regarded as a factor of exceeding wickedness, and as such to be suppressed by one or other of these well-known formulæ which occupy so much space in the book of faking. In doing this, it is apparent that the fact is lost sight of that sunlight clustered detail may be, and often is, of great beauty, and cannot be suppressed without at the same time destroying much of prime importance in the making of the picture. But detail is not infrequently the very essence of a picture. Take, for instance, the portrait of a laughing, girlish face, symbolic of all that is bright and joyous in youth. Here the delineation of the details of the expression, such as the sparkle of the eye, and the curves of the mouth, must be clearly defined if a true conception is to be formed of the real meaning of the photographic study. And to do this in the most efficient way a glazed surface print is a *sine quâ non*. Otherwise everything is so toned down to one level of uniform dullness that it is quite impossible, except by the merest guess work, to discover wherein the interest of the picture lies.

In this connection it is often forgotten that from mere considerations of size a photograph ought to approximate, in the methods of treatment, more to a Meissonier than to a Turner. To crowd, without a vestige of visible detail, a scene covering an area of miles or of yards on to a half-plate negative is to reduce what is an obvious absurdity. I do not wish in any way to advocate indiscriminate forcing into the forefront of all detail it is possible, fixed,

whether it be needed or not, but I do insist on the absolute necessity of depicting detail, strongly or not, according to circumstances, whenever its appearance is essential to the meaning or the making of a picture. And when detail, especially finely clustered detail, is to be shown, a highly glazed paper is, of course, the best to use. If, in lieu of this, a matt printing medium were employed, as is so often done, blurred masses without texture or parts 'would result, and the picture so manufactured could not be otherwise than an unpleasant travesty on the original. Neither must it be forgotten that apart from the magnifying power of glaze to accentuate the appearance of small items, glaze reflects a good deal of light, and by so doing further assists in approximating the finished print to that of the natural picture.

If further evidence were needed as to the genuineness of the error into which so many photographers have fallen through the indiscriminate use of matt surface printing this would be afforded by a reference to the methods employed by painters when dealing with similar subjects. If we visit the Royal Academy, or, indeed, any like exhibition at home or abroad, it will be noted that practically every canvas is finished with a highly glazed surface. This is effected not only by the laying on of one or more coatings of varnish, but also, in some instances, and in addition to the varnish, by the mixing of gloss-giving media to the actual pigments employed. Were varnish solely employed as a preservative, and were it detrimental from the artistic standpoint, it is perfectly certain it would seldom be applied till after the picture had passed the crucial test of its first public exhibition.

#### Common Subjects which call for Glossy Prints.

To sum up the whole question, though not by any means to exhaust it, it may be said, speaking generally, that the use of a glossy

paper is often more artistic than a matt one, because the form in the vast majority of cases, gives a better rendering of the meaning as well as the form and other pictorial items of a scene or subject. Glazed paper should always be employed whenever light is the characteristic of a picture, or is an important factor of it; whenever life and the proximate effects of life are its salient features, whenever it is desired to bring into prominence, or to distinguish detail which would otherwise be unrecognisable.

Amongst the "laws" governing composition none is more generally accepted than is that which insists that conspicuous incongruity be fatal to artistic success. And yet incongruity of a glaring type often deliberately created, simply by the substitution of matt place of glossy paper. For example, nothing could well be more incongruous than the effect produced by finishing with a dull, dead surface a photograph of a scene which owes much or all of its charm to the glint and glow of sunlight over it. The present swing of fashion's pendulum in the direction of ordaining the invariable use of a sombre surface for photographic prints is supported in no single instance by an acknowledged authority on art, and is backed by no reasons which can by any possibility be regarded as valid. In place of arguments we are given only adjectives; we are told that dulness and the absence of all distinctive detail are "artistic," are "beautiful," or are, perchance, "precious"; that murkiness means "mystery," "breadth," and "subtlety," and, *per contra*, we are informed that glossy printing is opposed to the "best interests of art."

On the other hand, the popular taste in continuing to use glazed printing media whenever the latter are most appropriate, that in the vast majority of cases, is supported not only by the obvious teachings of nature, but by the existing works of all those great painters who are acknowledged as masters by the cosmopolitan world of art.

F. GREENFELL BAKER.

## THE PRESENT STATUS OF COLOUR PHOTOGRAPHY.

A Paper Read Before the Photographic Convention, Southampton.

I WISH that the task of trying to give you a brief but coherent idea of the present status of colour photography had fallen to someone else's lot, for it is not the first time I have spoken on it, and it is always as well that a subject should be viewed from different standpoints.

My task is rendered all the more difficult because the recent exhibition organised by the BRITISH JOURNAL OF PHOTOGRAPHY has practically taken the wind out of my sails. This was an excellent exposition of colour-photography as now practised.

It is necessary to divide the subject into two main heads: First, the commercial application in the shape of photo-mechanical work, and, secondly, those processes which, requiring no mechanical power, may be used by any photographer, whether professional or amateur.

With regard to photo-mechanical processes, there is practically only one which is now of any importance, and that is the half-tone process. We are all of us more, or less familiar with the present status of this craft, or, at any rate, with the results. It is true that there are still faults and the inks are not in every case ideal, and in some cases one feels that there is more fine etching than should be required. To enter at any length upon these points would entail you being wearied and my transgressing that rule which says that papers must be limited to half an hour. The subject of the inks in particular has been ably treated by Sir Wm. Abney, and the outcry is still for those with ideal absorptions. I believe I am correct in saying that if more attention was paid to the precipitation of suitable dyes of the so-called aniline class, suitable as regards fastness to light, transparency, and correct colour absorption, we might get further advances. A generally accepted opinion is that all the aniline dyes are fugitive, but this is not so by any means. Of course, the chief fault of the half-tone process is the irritative effect of the cross-line screens; collotype is a long way ahead in this respect, but it was proved quite ten years ago not to be a commercial three-colour process, if regularity of results is to be kept in view.

I am not rash enough to say that we have reached finality in the photo-mechanical reproduction of subjects in natural colours, but advance is to be made, it can only be by the application of scientific facts and not to rule of thumb work.

Turning now to the second method, we must divide this into two classes—the direct and indirect processes. To the former belong practically only the Lippmann and the bleaching-out process.

Since Professor Lippmann, of Paris, gave, in 1891, details of his process of obtaining photographs in colours direct in the camera there has been no great advance; minor improvements there have been, but the very fact that it is necessary to use a perfectly transparent and grainless emulsion must, so far as I can see, limit the speed of the plate, with the result of proportionately long exposures. The fact, too, that the resulting pictures are upon glass, and can only be seen by reflection when viewed at a certain angle, must limit this process to the laboratory.

Professor Lippmann last year announced that after exposure of a film of bichromated gelatine in the camera in such a manner as to obtain interferential effects he had been able to considerably intensify the colours by first treating the film with potassium iodide and then with silver nitrate. By this process silver iodide would be formed in the luminated hardened gelatine. The colours were not only more vivid when viewed in the ordinary way, but the complementary colours were vividly seen by transmitted light. Bichromated gelatine is excessively slow, and so far has not been satisfactorily orthochromatised, so that there is little hope with this. If the same principle could, however, be applied to the ordinary Lippmann emulsion plates, it might be valuable to obtain negatives in the complementary colours.

Another process which will give us colours direct is that known as the bleaching-out process. In this, as you probably all know, a mixture of fugitive dyes is coated on paper, and exposed under a coloured original, and the dyes are bleached out by the coloured light that they absorb.

Dr. Neuhauss, who has paid considerable attention to this subject, uses a mixture of methylene blue, auramine, and erythrosine in a solution of gelatine, and increases the sensitiveness by the addition of chloral hydrate and caustic soda. Dr. Smith, of Zürich, who is placing a somewhat similar paper on the market, still adheres to the use of anethol, the camphor, of aniseed oil, and advises the backing of the paper when the printing is half finished with a sheet of blotting-paper saturated with hydrogen peroxide and alcohol.

You will note that this is a printing-out process from a coloured original, and so far exposures in the camera seem hopeless, for Dr. Smith's authority it is possible to obtain a result in the camera with an exposure of something like six hours. Should it be possible to increase the sensitiveness of this product so that it became possible to obtain a coloured result by any reasonable exposure in the camera, it would be very valuable, because with one such result the duplication or printing would be easy, as the colours obtained would in the same way reproduce themselves on a similar preparation, for red light bleaches out the blue and blue, leaving red, blue bleaches out yellow and red, and yellow bleaches out the red and blue. Intermediate colours of course, formed by the partial bleaching of two colours. There are many difficulties in the way to success, for the results depend upon the character of the light, sunlight not giving the same result as electric, and so on.

### Indirect Processes.

Indirect methods of colour photography are those in which three negatives of a subject are obtained through suitable red, green, and violet filters, hence the name three-colour photography, which embraces a whole series of processes.

There are, however, two main divisions—the first comprising the additive or optical synthesis methods, in which an image is formed either by projection with three-coloured lights, or the image is formed by reflection in an instrument such as the chromoscope such as I have on the table here. In both cases the transparencies are projected with or viewed by light, which is practically the same as the colour filter through which the negatives were taken.

While these methods are not such as appeal to every worker, because in the one case the triple lantern is a costly and cumbersome apparatus, and in the other because only one person can see the result at a time. In my opinion no results by any other methods can equal those obtained in this way.

Professor R. W. Wood, of Wisconsin, U.S.A., devised in 1899 a method of producing pictures in their natural colours by optical synthesis by means of three diffraction gratings ruled in different degrees of fineness on glass. Three constituent negatives are taken in the ordinary way through the usual red, green, and violet filters, and from these transparencies made by the usual photographic process. A sheet of glass is coated with bichromated gelatine and dried, and exposed to the transparency taken through the red filter, the coarsest ruled diffraction grating being placed in between; the whole is then exposed to sunlight, using parallel rays as far as possible. On the same plate is placed the positive from the negative taken through the green filter, with a finer filter interposed, and again exposed to sunlight, and the plate then developed with warm water. The third transparency, from the negative taken through the violet filter, is exposed, film side out, with a second bichromated gelatine plate, a still finer ruled grating being interposed, and then developed with warm water and dried. On bringing the two plates into accurate register and viewing them by transmitted light by means of an eye-piece, a picture in colours will be seen, the colours being formed by the decomposition of the light by those lines of the various diffraction gratings which were impressed on the bichromated gelatine, through the transparent parts of the positives used.

In 1904 Professor Wood improved his process and applied it to positives obtained by the Joly process—that is, positives obtained from the negatives taken through screens ruled with the three filters in closely contiguous lines. Gratings were ruled with three sets of lines in bands corresponding to the width of the red, green, and blue lines of the Joly screen. The positives from the Joly negatives were flowed with a thin solution of gelatine sensitised with bichromate of potash and dried. The triple ruled grating was then placed with its ruled surface in contact with the sensitive film, and exposed for a short time to light, and the plate then dipped in warm water and dried.

Quite recently Mr. H. E. Ives, the son of F. E. Ives, who has probably done as much as anyone for photography in natural colours from a practical point of view, has so far improved this process that in my opinion it can now be considered practical. He points out that the disadvantages of using Professor Wood's latest method are that one has to use a special grating, that one is constricted to the use of Joly pictures, and, further, that the Joly rulings themselves act

as gratings and give rise to false colouring due to the superposition of spectra.

I do not propose to enter into a detailed statement of all the arguments and facts that he deduces, nor to detail his methods of his early work, but to try and give you a succinct account of the plan he has finally adopted. Negatives are taken in the usual way through the usual colour filters; from these negatives transparencies are made by contact. A diffraction grating replica on glass having 3,600 lines to the inch is required, and some bichromated gelatine plates and a ruled screen, with at least 200 hundred lines to the inch, and with the opaque lines twice the width of the transparent. One of the transparencies is then projected by means of a lens on to the bichromated gelatine plate, the diffraction grating being placed in contact with the film, and then over this the ruled screen. The exposure is made, and the second transparency placed in position; the diffraction grating is now turned through an angle of  $21\frac{1}{2}$  deg., the ruled screen shifted so as to cover the exposed part of the film, and uncover a fresh strip; another exposure is made. The third transparency is then placed in position, the grating again shifted  $21$  degrees, the ruled screen again shifted to cover the two exposed lines, and the third exposure made. The plate is then washed in water to free it from the bichromate, and the operation is finished.

The shifting of the grating is to cause the blue, green and red to fall in their proper places, when the grating ruling is parallel to the slit, the blue falls on the plate, after a shift of  $21\frac{1}{2}$  degrees the green is on the plate, and with the second shift of  $21$  degrees the red; for as a grating is rotated as regards the slit, the spectra close in towards the slit.

The resulting plate, because you cannot call it either a negative or positive, simply has impressed on it the rulings of the grating at the above-mentioned angles, and only where the light passed through the transparency. When viewed in the hand the result is a colourless sheet of glass; but when illuminated by light from a slit and viewed by a lens or eye-piece, the colours are at once seen in very great brilliancy.

In order to obtain a great amount of light, Mr. Ives uses four slits, and thus obtains the superposition of two first and two second order spectra. The lines are so fine as to be absolutely invisible to the naked eye. This method is to be adapted for lantern projection, and it is hoped to find means to take the pictures directly in the camera.

From a scientific point of view this process is of very great interest, but I very much doubt, and this is entirely a personal opinion, whether it can ever become a popular commercial process. Dismissing any inherent difficulties in the working, and there may be some, I do not think that the public are going to be satisfied with pictures on glass or those that require a special apparatus to see them; such could not be given by Edwin to Angelina, or at least it would be inconvenient for the latter to carry about an instrument as big or bigger than a stereoscope, in order that she might, when she thought fit, gaze on the features of her beloved.

The process is extremely ingenious, and every credit is due to the inventor, who obviously bids fair to become the distinguished son of a more distinguished father.

### Subtractive Methods.

All other methods of obtaining photographs in natural colours are what are known as subtractive methods. That is to say, we start with a white screen or paper, and lay pigments thereon, and thus subtract something from the total white light.

Considering first those methods by means of which we can obtain transparencies that can be projected with any ordinary lantern: there are practically three principal processes, the Sanger-Shepherd, that of the Lumière N.A. Company, and Pinatype.

Taking these processes in order, I propose to briefly sketch the lines on which they proceed, and show you results by the same. I do not propose to enter into working details; those amongst you who dabble in colour photography are as well acquainted with the same as I am. Others must judge for themselves of the value of each and all the processes, and they have a very ready means of obtaining instructions for the same. Personally, I do not believe that there is much difference in results by any of the positive processes provided the negatives are correct.

First of all we come to the Sanger-Shepherd process. In this a positive is made from the negative taken through the red filter on an ordinary black tone lantern plate; this is developed, fixed,

thoroughly washed, and the image converted by means of ferricyanide and an iron salt into a blue image. From the negative taken through the green screen an image is obtained on bichromated gelatine containing a little silver bromide, the support being celluloid, and printing being done through the celluloid; the image thus obtained is developed in warm water exactly as in the carbon process, then stained up with a red dye, and superimposed on the blue image, and the celluloid stripped. In the same way a positive is made from the negative taken through the blue screen, and stained up in yellow, and the whole cemented and bound together.

In the Lumière process as worked in England, precisely the same procedure is adopted, only the blue image is obtained by the same process as the other transparencies, and stained up with a blue aniline dye.

The Pinatype process differs from the other two, in that the dyes used will not stain hardened gelatine; that is to say, in the last two processes the original negatives are used for printing, a relief in hardened gelatine is thus obtained, and this relief is stained up; whereas in the Pinatype process transparencies have to be made in the usual way, and from these the coloured transparencies are obtained.

A sheet of glass coated with bichromated gelatine is exposed under the transparency from the negative taken through the green filter, and after removal of the bichromate with a bisulphite bath, the image is stained in red. This red positive is treated to a weak bath of a copper salt and dried, then coated with bichromated gelatine, dried, and exposed under the transparency from the negative taken through the red screen, and then stained up with blue. The yellow image is obtained in the same way, or it may be obtained reversed, and used as a cover glass.

Mr. E. T. Butler has kindly lent me a few slides which are made by his process, which practically consists of dyeing the gelatine first, then bichromatising, exposing, and developing. These results are specially interesting, as they are from negatives taken, all three simultaneously, in a camera which Mr. Butler has invented.

#### Prints on Paper.

As regards obtaining colour results on paper, there have been a great many processes proposed or worked at one time or another. For instance, Drs. Miethe and Lehmann have suggested using the dusting-on process, in which successive coatings and dusting-on must be resorted to. Gum bichromate printing has also been used by Perscheid and others, principally continental workers.

Dr. Selle uses the property of certain dyes which stain bichromated gelatine hardened by the action of light more strongly than the unhardened, and proceeds as follows: "A sheet of glass is coated with a zinc-white collodion, which acts as the support for the coloured picture. On this collodion film a bichromated gelatine film is coated, and when dry exposed under one of the negatives. By washing in cold water the undecomposed bichromate is removed from the gelatine film, whilst the chromic oxide formed by the action of light remains behind. The print is now laid in an aqueous solution of a mordant dye of corresponding colour—that is to say, a dye which has the property of not staining pure gelatine, but of combining with the chromic oxide to form a so-called "colour lake"; thus only those parts of the gelatine film which have been affected by light will be dyed. When dry, the first image is coated with collodion and a film of bichromated gelatine coated on top of it. On this light-sensitive film the second constituent negative is printed, after the outlines are made to accurately coincide with those of the first image. The second print is treated like the first, and stained in the proper colour. Finally, after the second image has been coated with collodion, a third film of bichromated gelatine is coated on the top, and the third negative printed and dyed, etc. The finished print with the white collodion support may be easily stripped from the glass and mounted on a card. The colours are very permanent, because they are chromium lakes; yet no dyes appear to exist which possess all the properties which Selle's process requires. This is the principal reason why this interesting and really original process has not been introduced in practice.

Schmidt, of Berlin, also uses a similar process.

Reichel, of Munich, makes three-colour photographs by printing the three constituent negatives on collodio-chloride paper, tones them in special baths blue, red, and yellow, and then mounts them one on top of the other. For the red image a sulphocyanide gold

bath with sodium iodide and potash is used; the yellow print made by toning with lead, and the blue with iron salts.

Another process for the preparation of prints has been patented by Sanger-Shepherd and Bartlett. Three images are obtained on celluloid films as usual; these are stained with suitable dyes, the damp coloured film is brought into contact with paper coated with soft gelatine. The dye is transferred fairly quickly into soft gelatine, and when the dyed film is lifted up the colour image is seen on the paper. The same process is gone through with the two other constituent images, which must, of course, be laid on the paper so that the outlines coincide. The dye is sucked out of the image by the gelatine, and the celluloid images, which thus become colourless, can again be dyed, and can be used for making prints. Like the dye solutions, they are quite permanent. The process of printing may be examined from time to time by lifting up one corner of the paper.

Another process introduced by the Lumière N.A. Company is briefly as follows: The three constituent negatives are obtained in the usual way, and that taken through the red filter is varnished with celluloid varnish. A sheet of glossy bromide paper is soaked in water for at least half an hour, then, whilst wet, squeezed in contact with the red filter negative, and exposed, developed, and fixed. After thorough washing, the image is converted into a blue print. Prints from the other two negatives are now taken by printing bichromated gelatine films on thin celluloid, the celluloid being in contact with the film of the negative; then developed with water, and stained up in the red and yellow dye baths, and the three successively transferred on to the blue image, the celluloid being stripped in each case.

The Pinatype process was, I believe, demonstrated to you Monday evening. Briefly it is as follows: Transparencies are made in the usual way on ordinary plates; these are then printed on bichromated gelatine, and the plates thus obtained stained in the respective dyes, and gelatinised paper, after being well wetted, is squeezed in succession to the three-coloured plates, and the dye is transferred to the film of gelatine. The dyed print plates are kept, and may be repeatedly used, and only require restraining before each pull.

#### Carbon Processes.

Recently we have had commercially introduced three-colour carbon tissues. Those of the Rotary Photographic Company are coated on very thin celluloid, which is placed in contact with the film of the negative, so that double transfer is avoided. The Autotype Company use the double transfer process for their colour tissues and a semi-transparent temporary support.

The results obtainable by these processes are excellent, and there is nothing to learn, as they are nothing but the carbon process.

It is utterly impossible to give you any complete idea of all the methods which have been proposed and patented for obtaining transparencies and prints; to do this would compel us to undertake an all-night sitting. I have sketched in the principal processes those which we may justly consider as in practice.

Possibly I should mention Drac's process, in which no colour filters or screens are used, but the light is split up by means of prisms into definite sections of the spectrum, and these are used for making the negatives and projecting the transparencies.

Then there is an extraordinary process patented by Schinzel, which, if it can be worked, should be valuable, but I can see some difficulties in the way. Briefly, a plate is coated with three sensitive films, each of which is sensitised for a particular region of colours, and carries a colour screen in itself. After development and fixation the plate is treated with hydrogen peroxide, and the silver sets free nascent oxygen, which bleaches the dyes; then on removal of the silver the result would be a photograph in colours. There are other modifications suggested, but it looks rather visionary on paper.

Guthrie, of Berne, has patented a two-colour process, in which only one exposure is required. A chlorobromide transparency plate is dyed in an aqueous solution of naphthol orange and placed in film with a panchromatic plate, and the exposure is made through the glass of the transparency plate.

The orange-dyed transparency plate acts during exposure first as the sensitive plate for the blue rays, and secondly as a light-filter, which only permits the red, yellow, and green rays to reach the panchromatic plate. On the first plate there will thus be only

blue parts of the picture represented as black; on the second only the red, yellow, and green parts will be black. In other words, the transparency plate gives the negative for the yellow print, the panchromatic plate the negative for the blue print. The prints are made as follows: From the panchromatic (blue) plate, a Berlin blue print is made by any of the well-known methods, either by toning a transparency plate or bromide print or printing on ferro-prussiate paper. The transparency (yellow) plate, from which the stain is quickly removed by fixing and washing, is either printed on P.O.P. or on stripping collodion-chloride paper. The prints should be fixed with ammonia without rinsing, and will thus acquire a muddy yellow or yellowish red tinge. The yellow transparency is now directly combined with the blue, by placing the plates film to film. If a print on paper is required, the collodion print is transferred direct to the blue print. It is obvious, without further elaboration, that this process never gives us photographs in natural colours. Even if our eyes cannot directly recognise red in a landscape, yet in the multitude of compound colours red is always present. Moreover, the inventor admits that his process will not reproduce red. This naturally recalls the fact that plates with two such films and, further, plates with three films specially sensitised and bearing their own colour screens, are obtainable commercially; whether they are of any practical value I am not prepared to say.

### The Joly Process.

I have reserved to the last any mention of what we may justly call the one-plate processes. The first of these was that invented by Dr. Joly, our President of last year. In this process all the colour filters were ruled in parallel lines on one glass, and this was placed in contact with a plate, and the exposure was made through this compound line filter screen. From the negative thus obtained a positive was made on an ordinary black tone lantern plate, and this bound up in contact with a screen similarly ruled, only with the correct colours, which were slightly different to those of the negative making screens. This process was followed or was independently contemporaneous with the McDonough process, an exactly similar one. Sampolo and Brasseur had also a somewhat similar process, but these processes were not commercially successful. For one reason we had not satisfactory panchromatic plates, and another was that the ruling was comparatively coarse, so that when projected the lines were distinctly visible on the screen. The most important reason, to my thinking, for their non-success, lay in the fact that they were glass processes and would not give prints on paper.

Recently Powrie, in conjunction with a Miss Warner, of that city of recent infamous fame, Chicago, claims to have considerably improved the process. His method of making the plates is as follows:—

"Sheets of ordinary negative glass are coated with bichromated gelatine, and exposed to the light through a negative plate of transparent and opaque parallel lines. The light passing through the transparent lines of the negative renders the gelatine insoluble in warm water, the unexposed portions washing away, thus securing upon the glass colourless gelatine lines, which, with the plates now in use, are from 1-600 to 1-1,000 of an inch in width.

"The plate is then immersed in a colour bath of a suitable green dye, and then in subsequent baths to render the colour stable, washed and dried. The appearance of the glass is a delicate green tint. It is then recoated over its entire surface with bichromated gelatine, and again exposed to the light through the opaque-lined negative, taking the precaution to have the green lines protected by the opaque lines of the negative, and also one-half of the remaining unexposed surface.

"The plate is treated in a similar manner after this exposure as for the green lines, except that a red dye is now used, and the plate is rinsed and dried as before. The appearance of the plate is yellowish in tone. It is then coated a third time, again exposed, and passed into a bath of violet-blue dye. This gives the plate a neutral tint, from the recombination of the three elementary colours, the surface being completely covered without overlapping of the edges.

"It is possible by this photographic printing operation, with special machinery for aligning the plates and printing them automatically, to obtain remarkable uniformity. The increased fineness of the colour lines renders them invisible to the eye, and registration of the lines with a transparency would be impracticable.

"The next operation is that of coating them with a panchromatic emulsion, when they are ready to be exposed in an ordinary camera, developing and fixing in the usual manner, and obtaining a negative in colours. It is obvious that in this case the exposure must be made through the glass."

The negatives obviously show the subject in its complementary colours, and it is only necessary to print on a similar plate to obtain the colours as in nature.

### The Lumiere Process.

Recently, too, MM. Lumière, the distinguished chemists of Lyons, have patented the use of potato starch. This is sifted so as to obtain as far as possible starch grains of approximately the same size, then they are stained with the necessary filter colours, and mixed so that the mixture presents a uniform grey tint, proving that there is no preponderance of one colour over the others. The mixture is then sifted over glass which is rendered sticky, and the grains adhere. Now it is important that there should be no overlapping of the grains, and that the interspaces of bare glass left between the grains—for they are shaped something like an elongated oyster shell—must be filled up with an opaque material. They must also be protected by a varnish. There is also another point, and that is that starch is not transparent until imbedded in some material like Canada balsam. You will thus see that there are many difficulties to be overcome, and when this multiple filter plate is ready it has to be coated with a panchromatic emulsion.

The exposure is made, of course, through the glass, and after development and fixation the result is a negative not only as regards light and shade, but also colours; that is to say, the complementary colours are obtained, so that to obtain a positive one must either print on to a similarly prepared plate or convert the negative by one of the well-known methods into a positive direct.

Drs. Smith and Merckens, of Zurich, have patented the use of very small geometrical figures of all sorts for exactly the same purpose, and they claim that they can make a printing paper by the same means. These patterns are impressed on a gelatine plate mechanically, and the emulsion coated on top, the exposure being made through the glass.

Some such process as this, if practicable, will, I think, solve the problem of colour photography. One plate carrying its own filters, and a similarly coloured paper whereon to get our results; but if the latter, the coloured paper is impracticable, then we have means at our disposal in existing methods of obtaining prints in colours. What we want, as I have proved by being able to make a print from a Joly negative in colours on paper.

There is one fact I should like to mention before leaving this particular subject. All these one plate, mosaic, or line processes were outlined by the well-known French writer, Louis Duco du Hauron. In his work, "Les Couleurs en Photographie, Solution du Problème," published in 1869, he suggested the use of lines and dots for particular purpose, but it is not generally known that in a letter to M. Lelut, a member of the Institute of France, which was written in 1862, seven years previously, he points out that lines, dots and geometrical figures could be used. As a matter of fact, there are very few variants of three-colour photography that Duco du Hauron did not outline, although they have been the subject of recent patents.

### The Future Outlook.

Possibly I might say a few words as to the practice of colour photography. Recently it has been so simplified by the introduction commercially of satisfactory panchromatic plates, of excellent filters which absorb really very little light save that which they ought to, and easy printing materials, that it is a subject which should receive more attention than it does. What has stood in the way of its more general adoption, what still stands in the way, is the want of a camera which will enable us to take all three negatives at once, a camera which can be obtained at a reasonable price, is simple in construction and working. Given this, I am convinced that where we now have one colour worker we should have a hundred. The very fact that one must make three consecutive exposures limits our work enormously; whilst in the studio this is not felt so much, it is a great drawback for all outdoor work, where trees, cattle, etc., will not keep still just to please the photographer. It is pos-

sible that I am optimistic and prejudiced, and that the pictorial worker who loves to suggest rather than delineate an object, will smile at my ideas that colour photography in another few years will be the rule and not the exception, and will say that it can never be a means of pictorial photography because it will not allow him to make eccentricities. My answer is that it will place a still greater power in his hands because he cannot only destroy and alter form, but colour also.

The future of colour photography lies in a one-plate exposure on one-printing paper, but the intermediate step is the one-exposure three-plate camera, and three printings. Colour photography, as stands at present, has been commercially proved in Berlin, in London, and in Plymouth. There is a vast field open before it, not only in portraiture, but in every subject that has colour, and when we look around us it will be found that the exception in nature is monochrome, whereas in photography it is the rule. E. J. WALLACE.

## THE CONVENTION AND AFTERWARDS.

The Photographic Convention of 1906 is now ancient history, and most of its members have long ago got over the excitement of the week's meeting, and are looking forward with pleasurable anticipation to the time when they will meet again, under similar conditions of fraternal goodwill, good weather, and jolly good time. But to me as a professional, the Southampton convention was more than a mere holiday; it afforded an opportunity of meeting with friends new and old, among which are numbered many of our leading workers and business men, with whom it was both pleasurable and profitable to compare notes, and to discuss matters which can only be of real interest to the man who has to earn his bread by means of photography.

It also tended to enlarge one's sympathies towards one's weaker brethren, and gave the opportunity for giving more than one what may prove to be helpful counsel and advice.

It brought one into intimate contact with manufacturers and dealers, men whose products we have been using for years; and gave the opportunity for paying off old scores, other than financial, in a spirit of mutual friendship and bon amie.

It gave one also the pleasure of meeting with the leaders of thought in the photographic world, both scientific and journalistic, some for the first time; and their helpful and instructive communications, both from the platform and in personal conversation, cannot fail to stimulate a keener interest in photography, in both its artistic and its scientific aspects, and to make even the hardened professional feel that there is still something to mark, learn, and inwardly digest, if he would keep pace with the rapid development of photography in all its higher methods and advanced possibilities, and that if he would rise above a position of mediocrity he must embrace the opportunities which are before him, and seek to elevate himself to a higher plane of experience, both in theory and practice.

While these and other features in connection with the Convention must be of general interest to all professionals who have the future of photography at heart, it is surprising to know how few really working professionals attend the annual meetings. Is it not because as a class they are so conservative and narrow in their relations toward their fellow craftsmen, even unfriendly, and sometimes-unkind and unjust, especially towards those who are in the same line of

business in the same town as themselves? Is not this the reason why the Professional Photographers' Association is not the powerful organisation it was designed to be? Why the old Benevolent Association came to an untimely end? Why all the proposals for the elevation of professionals have met with such ignominious failure? Is not the spirit the cause of the cutting of prices, and the general lowering of the business in the eyes of the public, which is also one of the causes of the depressed state of photography as a business to-day? And the question which thoughtful men are asking is, "Where will it all end?"

The greatest lesson which I learn from the Convention is that in we have a neutral ground, where all professional disabilities may be forgotten, and where a fraternal fellowship may be fostered, and larger-heartedness cultivated. I am more than ever convinced that if photographers would fraternise more, it would be to their mutual advantage, and would do much towards removing the strained relationship which now exists between them, especially in this country. In America things are different. Over there photographers meet in friendly conclave, and freely discuss business methods such as advertising schemes, unfair competition, scales of charges, etc., and generally aim to improve the business status of the profession. Is not this kind of thing possible in this country? If it is, then the annual Photographic Convention is a convenient and ready-made means of bringing it about, which I feel should be taken advantage of.

I am aware that such a meeting of professionals was proposed in connection with the recent meeting at Southampton; but so few really working professionals were present, and so little interest taken in the idea, that it fell through. I hope that before the next meeting of the Convention, I shall have the opportunity of again bringing this matter forward, and of co-operating with the able and genial hon. secretary, Mr. F. A. Bridge, in bringing it to a successful issue.

I may add that it is quite an aspiration and a personal privilege to come into friendly contact with such an honest, large-hearted man as Mr. Bridge, and no professional can attend a convention under his supervision without imbibing a large share of his friendly spirit, which will send him back to his business a better man, both in mind and heart.

HENRY J. COMLEY.

## FOREIGN NOTES AND NEWS.

### Dark Room Illumination for Working Red Sensitive Collodion Emulsion.

Herr Fritz Haberkorn contributes a useful little note to the current issue of the "Photographische Korrespondenz," and, while it has reference particularly to the use of red sensitive collodion, it is obviously also applicable to gelatine plates. He points out the danger of using a red illumination, and gives the following formula for the preparation of a deep green screen:—

Gelatine .....	12 gms.
Distilled water .....	200 ccs.
Allow to soak for an hour, and then melt by the aid of a water bath and add	
Blueish acid green (Hoechst) .....	3 gms.
Then add	
Tartrazine solution 3 per cent. ....	1.2 ccs.
Naphthol green solution 4 per cent. ....	2 ccs.

Stir well and filter, whilst hot, through felt. Plate glass should be thoroughly cleaned, then rubbed with a 0.5 per cent of potash water glass and accurately levelled. To every 100 qcm. of glass allow 7 ccs. of the dyed gelatine. Two such screens are required, and one should be coated with matt varnish. If possible, also, a sheet of ground glass should be placed in the lantern between the light and this screen, as it cuts off a good deal of the heat; then the matt varnish can be omitted.

For tank lamps a solution of the following composition may be used:—

Distilled water .....	800 ccs.
Blueish acid green 2 per cent solution .....	25 ccs.
Naphthol green 4 per cent. ....	1.5 ccs.
Tartrazine 3 per cent. ....	1.2 ccs.

This is for an internal width of 2½ cm.

In order to test the efficiency of these screens, a plate coated with Albert's rapid red emulsion was exposed behind a Chapman-Jones

nitometer at a distance of 30 cm. for five minutes, and then developed. The different screens used were:—1. A combination of copper ruby glass, a dark yellow, and a bright yellow ground glass; König's methyl violet and tartrazine screen; 3. Two glasses coated with Albert's green collodion, one with matt varnish; 4. Two of the above described glasses, one with matt. varnish. (The size of all the screens was 33 cm. square, and the light a 16 cp. incandescent electric lamp.) 5. Stenger's lamp filled with the fluid above given. The results were as follows:—

Combination.	Spectrum Transmitted in $\lambda$	Last Number Visible.	Relative Quantity of Light.	Appearance of Plate.
1	610-710	—	—	Totally fogged, no numbers legible.
2	670 7 0	—	—	
3	4-5-575	15	24	Clean.
4	490-530	10	128	
5	49-525	9	192	

his proves that 1 and 2 are quite useless, and that 4 and 5, whilst more brilliant, are from four to eight times safer than Albert's green collodion. The region  $\lambda$  490—530 practically excludes F and E, and comprises the little  $b$  group.

#### Caseine Papers.

M. Macaire gives the following formula in the "Photo Magazine" for preparing a print-out paper with caseine, and it is stated to have all the good properties of albumenised paper and none of its disadvantages. Fifty kilos of commercial caseine are mixed with one kilo of caustic soda or potash and 100 kilos of water, and then vigorously beaten up till the caseine is thoroughly dissolved, and allowed to stand for 48 hours. The mixture is then filtered and the caseine precipitated by the addition of acetic acid, and the magma washed till there is no longer any trace of acidity, then rinsed with alcohol and a little ether to remove the traces of water, then allowed to dry spontaneously in the air and powdered. The result is pure caseine.

To make the sensitive emulsion the following formula is used:—

Alcohol .....	130	parts.
Pure caseine .....	10	parts.
Heat on a water-bath at 100deg. F. and add		
Glacial acetic acid .....	9	parts.
Calcium chloride (anhydrous) .....	1.25	parts.

Dissolve and add		
Absolute alcohol .....	10	parts.
Citric acid .....	2.5	parts.

Dissolve and add		
Alcohol .....	10	parts.
Camphor .....	3	parts.

Then add the following, which should be heated to 100deg. F.:—		
Water .....	30	parts.
Absolute alcohol .....	10	parts.
Silver nitrate .....	10	parts.
Glycerine .....	3	parts.

After coating, the paper should be dried for two hours at a temperature of 100deg. to 110deg. F. The paper is printed and toned exactly like any ordinary gelatino or collodio-chloride paper.

#### The Stereo Tel phot.

M. Vincent describes in the current number of the "Photo-Révue," an instrument which he has designed for stereoscopic work at long distances by means of which the inversion of the images is avoided. The apparatus is an adaptation of Vautier-Dufour and Schaefer's telephot, which was described in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1903, p. 589.

The principle of the apparatus is as follows:—At O and O<sup>1</sup> are the two lenses, at M, M<sup>1</sup>, and N, N<sup>1</sup>, are the plane mirrors. The rays transmitted by the lens O are reflected by the mirror M on to the mirror M<sup>1</sup>, and thence on to the left-hand half of the plate P. The rays from the left-hand lens O<sup>1</sup> are reflected by the mirrors N and N<sup>1</sup> to the right-hand side of the plate P. The separation between the two lenses was 29 cm. (= 11½ inches), and the focal length was 70 cm. (= 27½ ins.). The images are in the correct position, and the prints are obtained without any inversion. By means of a pocket stereoscope the images on the ground glass can be ex-

amined, and one can tell whether the relief is little or too great. The focussing of the two lenses is quite independent. When, in spite of the great differences between the various planes, one has to

use a large aperture, one lens is focussed for a near point and the other for a distant plane, and when examined in the stereoscope the image appears perfectly sharp and is superior to that obtained when both lenses are focussed on one middle plane.

## Exhibitions.

### RUGBY PHOTOGRAPHIC SOCIETY.

The 1906 exhibition of the above society will be held in the Benn Buildings, Rugby, on Wednesday, Thursday, Friday, and Saturday, November 14th, 15th, 16th, and 17th. Judge: R. Child Bayley, Esq., F.R.P.S. (Editor of "Photography"). Open Classes: A. Landscape, seascape, and river scenery; B. Architecture (interior and exterior); C. Any other subject not classed above; D. Lantern slides (sets of four). Awards: In each class the judge will have placed at his disposal a handsome bronze plaque, specially designed, and a silver medal. Entries close on Wednesday, October 31, 1906. Entry forms and further information respecting the exhibition can be obtained from Mr. R. H. Myers, hon. secretary, 13, Bridget Street, Rugby.

## Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patent were made between July 9 and 14.

FLASH LAMPS.—No. 6,705A. Ignition device for flash lamps actuated simultaneously with the instantaneous shutter of photographic apparatus. Wilhelm Venier, 18, Southampton Buildings, London. (Date applied for under Rule 5 of the Patents Rules, 1905, March 20, 1906.)

PHOTO-PRINTING APPARATUS.—No. 15,574. Improvements in photo-printing apparatus. Joseph Halden, 17, St. Ann's Square, Manchester.

TELESCOPIC CAMERA ELEVATOR.—No. 15,660. Portable telescopic photographic camera elevator. Edmund Healiss Harrison, 87, Fairholme Road, Croydon, Surrey.

PROJECTION APPARATUS.—No. 15,729. Improvements in or relating to optical projection apparatus. James Tiburce Felix Conti, 53, Chancery Lane, London. (Date applied for under the Patents Act, 1901, July 13, 1905, being date of application in France.)

PHOTO-MECHANICAL PRINTING.—No. 15,658. Apparatus for photo-mechanical printing. Benjamin James Hall, 41, Castlenau, Barnes, Surrey.

### COMPLETE SPECIFICATIONS ACCEPTED

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

THREE-COLOUR CAMERA.—No. 14,623, 1905. This invention relates to cameras for obtaining three photographic views simultaneously

upon the same plate; such views being practically free from differences due to stereoscopic effect. The camera is divided into three compartments, arranged side by side; the back of each compartment being open to three different portions of the same sensitive plate. In front of the central compartment are arranged, side by side and close together, three small lenses, which may be of the same or of different focal lengths. Or they may consist of three different strips or portions of a single lens. Assuming, for the purpose of description, that three lenses are employed, the rays which pass through the two outside lenses are, by means of mirrors, deflected to the right and to the left respectively. These rays are, by means of other mirrors set at suitable relative angles, again deflected and ultimately reach the right and left hand portions of the sensitive plate. Meanwhile, the rays which traverse the central lens pass direct to the central section of the sensitive plate. In the path of the rays traversing the central lens, another lens preferably adjustable in the direction of its focal axis, is arranged; and between each outer section of the sensitive plate and the mirror pertaining thereto is also arranged a lens; these supplementary lenses enabling the focal length of the rays passing through each outer lens to be adjusted and made equal to that of the rays passing through the central lens, thereby ensuring the production upon

Fig. 1.

the sensitive plate of three pictures of exactly equal size. In place of mirrors, it will be obvious that prisms may be employed. It can also be perceived that what may be described as the two "outside" cameras may be of fixed and equal focal length, whilst the central lens is of a different focal length, there being arranged within the central section of the tri-part camera an adjustable lens whereby the size of the image thrown upon the central section of the sensitive plate may be regulated to correspond with that of the images thrown upon the outer sections of the said plate. Or the focal length of the central camera may be treated as normal, and lenses employed in the two outside cameras for the purpose of adjusting the focal length pertaining thereto to that of the central camera. The apparatus may, therefore, be constructed with either one, two, or three pairs of lenses; but in all cases at least one pair is necessary, in order to equalise the focal lengths of the three members of the tri-part camera. When it is desired to use the apparatus in connection with colour screens, the lenses may be uncorrected for chromatic aberration; the distances apart of the compartments pertaining to the respective pairs of lenses being altered to suit the different focal distances yielded by the different colours. The brightness of the three images may be varied by varying the extent to which the three lenses are respectively screened. The accompanying drawings illustrate diagrammatically a tri-part camera adapted for carrying my invention into effect; Fig. 1 being a longitudinal section of one form of the apparatus, whilst Fig. 2 is a similar view illustrating an alternative mode of construction. A is the camera divided into three compartments

$a$   $a'$   $a''$  and B C D are three lenses or three portions of a single lens arranged opposite the central compartment  $a'$ . Referring more particularly to Fig. 1, it is assumed that the focal length of the outside lenses B D are equal to one another, but a greater than that of the central lens C.  $b$   $d$  are mirrors mounted respectively at the rear of the lenses B D and at an angle of 45 deg. with the focal axes thereof. These mirrors reflect rays of light passing through the lenses B D to mirrors  $b'$   $d'$  arranged in planes parallel with those of the mirrors  $b$   $d$  opposite to lenses B<sup>1</sup> D<sup>1</sup>, which latter are respectively mounted in the compartments  $a$   $a''$ . The lenses B<sup>1</sup> D<sup>1</sup> are preferably the meniscus type, and are so disposed that the focal length of each pair of lenses B B<sup>1</sup>, D D<sup>1</sup>, is equal to that of the single lens C. The several sets of lenses are so arranged that there is no appreciable distortion of the several images thrown upon the sensitive plate  $a''$ ; and being, moreover, of equal focal length, the images thrown upon the several portions  $a$   $a''$  the sensitive plate correspond with one another in size. The lenses B C D are preferably mounted within the camera, shown, in order to facilitate the proper transmission of the rays to the mirrors  $b'$   $d'$ .  $e$   $e$  are adjustable screens or slides for preventing too wide a dispersion of the rays passing through the lenses B D. The mirrors pertaining to the pairs  $b$   $b'$  and  $d$   $d'$  are each mounted on slide adapted to enable them to be adjusted in such a way that the central portion of the image to be reproduced is reflected upon the central part of the sensitive plate allotted thereto. The lenses B<sup>1</sup> D<sup>1</sup> are also mounted

Fig. 2.

as to be capable of adjustment. According to the modification illustrated in the diagram Fig 2 prisms  $b^3$   $b^4$  are substituted for the mirrors  $b$   $b'$  before referred to, and prisms  $d^3$   $d^4$  are substituted for the mirrors  $d$   $d'$ . In this construction, the normal focal length is assumed to be that pertaining to the lenses B D and the focal length of the lens C is accordingly increased and rendered equal thereto by the introduction of the plano-concave lens C<sup>1</sup>. In this case, the optical centre of the pair of lenses C C<sup>1</sup> is in front of C and is at a focal distance from the sensitive plate equal to that of the lens B in conjunction with its reflecting prisms  $b^3$   $b^4$ , or of the lens D in conjunction with its reflecting prisms  $d^3$   $d^4$ . It will be obvious that the triple lens B C D may be formed as an integral body or as three separate lenses arranged side by side; and formed so that the lens C<sup>1</sup> may, if preferred, be combined with the lens C. The claims are:—1. The herein described camera adapted for the simultaneous and parallel production of three precisely similar photographic views free from stereoscopic effects; the apparatus comprising a chamber, divided into three compartments in each of which a sensitive surface is exposed, and a centrally arranged tri-part lens, the ray which passes through the central portion of the lens being led direct to the sensitive surface exposed in the central compartment, whilst the rays which pass through the lateral portions of the said lens are deflected and respectively transmitted by means of reflectors to the sensitive surfaces respectively exposed in the two outer compartments; a lens of a character adapted to render the focal length of each of the latter lenses equal to that of the direct or central lens being placed in the focal axis of each of the reflected or outer rays,

substantially as set forth. 2. The herein described modified mode of constructing cameras of the kind and for the purpose referred to in the preceding claiming clause, according to which a lens is placed on the focal axis of the direct or central ray and its focal length altered to coincide with that of each of the reflected or outer rays which respectively pass through the lateral portions of the tri-part lens, substantially as set forth. William de Wiveleslie Abney, K.C.B., Measham Hall, Derby.

**PRINTING FRAME.**—No. 18,195, 1905. This invention is for printing bromide and other gaslight papers by daylight, and is effected by means of a frame similar to an ordinary printing frame. A groove on each side of the front or exposing surface is made in these grooves, a slide moves to and fro over the exposing aperture in the frame, the slide has a slot across, of any width not exceeding that of the exposing aperture in the frame, each end of the slide must be rather wider than the aperture to prevent light entering before or after exposure. By passing the slot over the negative the picture is printed, one movement is sufficient for bromide paper with a good negative, but for gaslight papers with a bad light or dense negative so many passes are required that it is necessary to divide the slide crosswise, by this means time exposure can be made. As this method will not answer for gaslight and bromide papers with a good light and thin or even proper negatives, the slides are connected with a clip on each side of the slide. The claims are:—

1. A means of printing by daylight, bromide and other gaslight papers by the use of a slide or slides working in grooves made in an ordinary photographic printing frame, the said slide or slides having a slot and employed as hereinbefore described. 2. A means of obtaining equal results with the various densities of negatives and different degrees of light by the use of a regulating slide, to operate the slot in the said slide or slides and employed as hereinbefore described. William Gale, 4, Smart's Lane, Loughton, Essex.

**FOCAL PLANE SHUTTERS.** No. 20,528, 1905. The purpose of this invention is to provide a convenient and reliable means for regulating the opening in focal plane shutters. This is effected by means of spring grips operated by external means. The blind is of the ordinary opaque kind, and is attached to rollers in the usual manner. To one roller is fixed the lower section of the blind, its free end being connected to adjusting tapes. To the spindle on which the said roller turns is an extended pivot to which is fixed the usual winding knob, detent, and tension indicating dial. The roller is formed of a hollow cylinder which freely fits the spindle on which it turns, but is prevented from erratic movement by means of a light friction spring situated between the spindle and the inner surface of the said cylinder. At the ends of the latter and securely fixed to the said spindle are solid bosses on which are fixed narrow adjusting tapes attached at their opposite extremities to the lower blind. Each section of the blind is sufficiently large to entirely cover the exposure aperture, one part performing this function before, and the other after exposure, and their free ends are provided with suitable stiffening strips to prevent the material from sagging. The section of the blind attached to the adjusting roller is provided at each side of its free end with flat spring clips, which normally grip the tapes and firmly hold the sections of the blind at a given degree of separation. When it is required to alter the width of the slit, the blind is first allowed to run down. This will bring the spring clips directly underneath the pressure feet. A lever is then depressed, which causes the pressure feet to release the grip of the springs and admits of the free rotation of the bosses in either direction, the reserve run of the spring roller taking up the feed in one direction and giving way in the other direction, and consequently altering the width of the opening as may be required. During the process of adjusting the slit the top blind is held stationary by the pressure feet retaining the spring clips in position, and the adjustment is brought about by turning the setting gear. The spring detent connected therewith being for the time placed out of action. The raising of the lever, operating the pressure feet, allows the spring clips to again grip the tapes. The claims are for:—1. In a photographic shutter of the focal plane type of the method of regulating the width

of the slit or opening in the roller blind, by means of spring clips engaging or disengaging adjusting tapes, the said spring clips being opened or closed at will by external means substantially as and for the purpose described. 2. The combination in a focal plane shutter of a spring roller and a composite roller, the latter being formed of a cylinder carrying a section of the roller blind, and end bosses, to which adjusting tapes are attached, the said bosses at times having independent movement to the said cylindrical roller, such movement being controlled by the setting mechanism substantially as and for the purpose described. 3. A lever operated link, or strip, provided with pressure feet which open spring clips connected to one section of the roller blind substantially as and for the purpose described. 4. A sliding spring controlled detent in combination with a rocking detent, the former acting as time catch when moved longitudinally in the path of a time stop, and the latter as a pawl or click in conjunction with the winding gear, also as a release when making exposures, substantially as and for the purpose described. 5. A sliding cam plate provided with slots, and cams, for operating the pressure feet, the sliding time detent, the pivotted detent, and the adjustment stop, substantially as described and illustrated in the accompanying drawings. Magnus Neill, 140, West Twenty-third Street, New York, U.S.A.

**LUMINOUS TRANSPARENCIES.**—No. 21,913, 1905. The invention refers to an improved method of mounting transparencies so as to produce luminous reflections and brilliant colour effects. These results are obtained by placing behind a transparent photograph on convex or flat glass i.e., a glazed film, a brilliant, coloured background, which may be in contact with or placed at some distance behind the film, said background consisting simply of a coat of coloured varnish applied on an opaque backing with a glossy or matt surface; or, more generally, of metallic sheets called foils of various shades, or sheets of aluminium or any other bright metal; or of enamelled plates, varnished or bright; or of paper, cardboard, gelatine, or celluloid of a shiny appearance, coloured, nacreous, lustrous, glazed, iridescent, watered, marbled, frosted, gilt, silvered, coppered, bronzed, in a word, with a brilliant surface; or it may consist of a shiny woven material of any colour, such as: brocade, spangled cloth, gold, silver, silks, satins, velvets, plush, etc.; or it may consist of a brilliant and coloured surface. The claim is for a method of mounting transparent positive photographs for the purpose of obtaining new diaphanous, transparent, and brilliant effects in monochromes and polychromes, said method consisting in the application of a coloured and brilliant background behind or under transparent photographs or the like on flat or convex glass, so as to give the photographs the peculiar effects of diaphaneity or transparency, brilliancy, colouration, and luminosity set forth in the above specification.—Fernand Georges Paul de Neuville, 132, Rue du Faubourg, Paris.

**DEVELOPING DISH.**—No. 3,479, 1906. This invention relates to an improved developing dish which has a well or sunk centre into which the plate fits, and a depression so that the fingers can lift the plate. The sides of the dish are curved over so as to prevent the liquids from spilling over the edge and a spout partially covered in is formed at one corner of the dish. The claims are for:—1. An improved developing dish which having a well in the bottom requires less chemicals to flood plates, and also keeps plates from slipping to ends of dish. 2. An improved developing dish having a small indentation or sunk portion between the edge of well and side of dish, by means of which indentation the plate can be easily lifted out of well, either by the finger or any appliance for that purpose. Lewis William Donne, 181, Upton Lane, Forest Gate.

The following complete specification is open to public inspection before acceptance under the Patents Acts, 1901:—

**PHOTO-MECHANICAL PRINTING.**—No. 11,071, 1906. Photo-mechanical printing. Ippers.

## New Materials.

Velox Carbon "Vigorous." Sold by John J. Griffin and Sons, Limited, Kingsway, W.C.

This particular type of Velox carbon has been lately improved, so as to do away with the tendency to veiled high lights and stained prints, too often met with when a slightly oxidised developer is employed. Our trials have been very satisfactory, and we have not met with the troubles of veiling or staining, although an old developer was used. The paper certainly deserves its name of "Vigorous," for the prints are extremely rich and plucky. Using an actinometer with H. and D. squares, increasing in geometrical progression, we found that seven steps were recorded, that is, from bare glass, reckoned as unity, to 64, which corresponds to a H. and D. density of 2.1, a range which comprises most negatives that one can print. The sudden drop, however, from under this density to pure whites is very striking, and proves that the paper will be particularly suitable for obtaining good results from somewhat thin negatives.

### CATALOGUES AND TRADE NOTICES.

The July number of the "Camera House Journal, Butcher's Business Bulletin," is to hand, with seasonable and novel lines.

Messrs. Dorrett and Martin send us a price list of their tinted miniatures with celluloid, the surfaces, and mounts for the same, and inform us that they have been compelled to transfer this part of their business to larger premises, fitted up with the latest apparatus, etc., so as to enable them to cope with the increase in this branch. Their new address is 16, Belle Vue Road, Upper Tooting, S.W.

## Commercial & Legal Intelligence.

SYDNEY PORTER, of New Road, Chippenham, photographer.—The liabilities expected to rank for dividend amount to £229 12s. 9d., and the deficiency is explained at £137 13s. 5d. According to the Official Receiver's observations, the debtor, who is forty-nine years of age, states that he commenced business about twenty-five years ago as a photographer with about £40 capital. He attributes his position to "bad trade and keen competition."

J. J. WADDINGTON.—To take over the engraving and photogravure business lately carried on by J. J. Waddington, Limited (incorporated in 1901), and to adopt an agreement with E. W. Hunter. No initial public issue. First directors (not less than two nor more than five): E. W. Hunter and H. N. Hunter, £50. As fixed by company, 6, Henrietta Street, Covent Garden, W.C.

SOUTHWARK Photo Engraving Company, Limited, London, S.E.—Lien registered July 13, for £600 five-and-a-half per cent. debentures; no trustees; charged on the whole of the undertaking.

A WICKED FRAUD.—A remarkable prosecution took place at Birmingham on Friday, when two photographers' canvassers were charged with travelling to Walsall without paying their fares. Benjamin Cohen, photographer and art dealer, was summoned for aiding and abetting the defendants, who were in his employment. Mr. Lambert, of London, who prosecuted for the L. and N.-W. Railway Company, said the defendant Cohen employed many canvassers in his business who travelled the Midland Counties. He took out two monthly third-class season tickets to Walsall in the names of Francis Wasp and Dennis King, two of his travellers. These travellers were required to return their tickets to the office every night, and frequently they were transferred and used by female canvassers. On some occasions the girls travelled without tickets at all, and, when asked for their tickets, said they had left the season tickets at home, giving the names of Wasp and King. They said they had protested to Cohen against the use of these tickets, but they were compelled by Cohen to use them. Sir Walter Fisher, the presiding magistrate, said it was one of the most wicked frauds it had ever been his lot to listen to. How could honest traders compete with a man who was sending his canvassers about the country without paying their railway fares? They would fine Cohen £2 and costs for the first offence, or a month's imprisonment, and £10 and costs in the second case, or two months' imprisonment. The summonses against the canvassers were dismissed.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July	Name of Society.	Subject.

		General Meeting.

## News and Notes.

WHEN a Sunday-school excursion from London visited Sheerness last week, seven youths belonging to the party walked along beach in front of the fortifications. Two of them carried cameras and they had snapshotted two warships and another vessel when they were stopped by the soldiers on duty. They were taken to the garrison, and afterwards to the police station, where the negatives were examined. It was found that no photographs had been taken of the fortifications, and inquiries showed that the youths had no intention of infringing the regulations against photographing the defences. They were not detained, but the plates of the two warships were kept.

LAST week the president of The Bristol Photographic Club, Mr. John Fisher, gave to members and friends a most delightful critical address upon the qualities, from an art point of view of the portraits by Herr Duhrkoop, which were lent by THE BRITISH JOURNAL OF PHOTOGRAPHY. Mr. Fisher said that the standard set by the pictures was so high as to be quite bewildering. Indeed, he thought that their effect upon a true artist would be discouraging for the very reason, but, he added, the effect upon a true student would be highly encouraging and stimulating on account of the possibilities they revealed. Herr Duhrkoop's work proves that he is a cultured artist—a man who goes straight to Nature in her simplest form, and who portrays ordinary everyday scenes with such skill that it confers ease, grace and beauty upon them. Mr. Fisher then proceeded to analyse various pictures individually.

NOTICE has been given by Mr. Bottomley of his intention to ask the Under-Secretary of State for the Colonies whether his Majesty's Government will consider the propriety of making a friendly representation to the Natal military authorities in favor of substituting photography for decapitation as a means of identification in the field.

At the recent annual meeting of the Huntingdon and District Amateur Photographic Society the proceedings were adjourned, on a proposition that the Society be broken up owing to lack of interest. The adjourned meeting was held last week, when Mr. W. C. Bernard was in the chair. After a discussion the proposition to break up the Society was withdrawn, and it was agreed that a special committee of three be appointed to consider what steps should be taken to increase the membership and stimulate the interest in the doings of the Society, and Messrs. E. Trench Smith, W. J. Trehearn, and W. Murton were elected to form the special committee. Mr. W. C. Bernard was again elected President for the ensuing year, and the following gentlemen were re-elected vice-presidents:—Messrs. F. B. Thackray, J. W. Tysoe, A. G. Dilley, and the Revs. Hedley Vicars and G. R. Holt Shaffo. Mr. W. D. Storey was elected hon. treasurer, and Sergt. Trehearn was re-elected hon. secretary, while the following were elected on the committee: Messrs. J. Pascoe, Sergt. Major Page, B. Allen, W. Murton, and E. Trench Smith. It was agreed to send out the portfolio on the 18th of August, the subject agreed on being "Flowers."

The council of the Royal Meteorological Society, with the view of advancing the general knowledge of meteorology, promoting an intelligent public interest in the science, and making the work of the society more widely known, last year appointed a lecturer to act in co-operation with scientific societies, institutions, and public schools in various parts of the country. The success attending the project was so marked as to lead the council to continue the appointment for another year. The lecturer, Mr. William Marriott, F.R.Met.Soc., is prepared to deliver lectures on the following meteorological subjects:—(1) "A Chat about the Weather," (2) "Weather Forecasting," (3) "Rain, Snow, Hail, and Thunderstorms," (4) "The Upper Regions of the Atmosphere," (5) "Clouds, Fog, and Sunshine," (6) "Climate and Health," (7) "Meteorology in Relation to Agriculture," (8) "How to Observe the Weather" (elementary). The lectures will be illustrated by lantern slides. Particulars as to the fees for the lectures and as to the terms on which the exhibits can be lent may be obtained from the assistant secretary, Royal Meteorological Society, 70, Victoria Street, Westminster, S.W.

"THE Holidays 1906, where to stay and what to see," is the title of a book published by Walter Hill and Co., 67, Southampton Row, W.C., and as its title implies, deals with holiday resorts on the Midland, L. and N.W., G.N., G.E., G.W., and Great Central Railway Companies' lines. It is a useful local and general guide to many places.

SOME strikingly effective advertisement matter has been sent us by Mr. A. H. Pitcher, of College Court, Gloucester. Excellent examples of various cross lines screens suitable for fine and cheaper papers, with a few, but telling lines underneath, are just such as appeal to the local tradesman, who may be getting out a catalogue. Mr. Pitcher has also succeeded in obtaining insertion in the local paper of a very effective free advertisement of the acceptance by H.M. the King of some enlargements made by him.

THIS year's meeting of the British Association is to take place at York, from August 1 to 8. In the preliminary reports we note, among other subjects of direct or indirect photographic interest, that Sir Wm. Ramsey and J. F. Spencer will read a paper on chemical and electrical changes induced by ultra-violet light, which contains some important new matter as well as a summary of what is at present known on this subject. Mr. H. Stansfield will read a paper on photographs of thin liquid films, and Prof. Barton and J. Penzer on photographic records of a string's vibration and responsive notions in the air. Several semi-popular afternoon lectures are also to be illustrated by lantern slides.

THE Yorkshire Photographic Union have just issued their latest list of lecturers for the 1906-7 season, and a goodly list it is too.

THE "Professional Photographer" for June and July is just to hand from Kodak, Limited, and it is, like the first number, excellently printed, and will be found useful by professional photographers, to whom alone it is issued.

THE newly fitted up dark room of the Dublin Camera Club was formerly opened on the 16th, at a duly summoned meeting of the club. Mr. W. H. Ebbs read a paper on negative making, and afterwards by kind permission of Lafayrth, Ltd., gave a demonstration on the process of development.

THE first Annual Photographic exhibition and Competition of the Dumfries and Maxwelltown Photographic Association takes place from October 11 to 13. The prospectus is an attractive one, for, besides classes confined to members of above society, and a class for the members of the Scottish Photographic Federation, there are four different open classes comprised of (1) landscapes and seascapes; (2) portraiture and general; (3) miscellaneous; (4) lantern slides. The prizes have to take the form of silver and bronze plaques and medals, and at least two prizes will be awarded in each class. Jas. Patrick, Esq., Edinburgh, the well-known Scottish Federation judge, has agreed to come down to Dumfries in that capacity. Prospectuses and Entry forms may be had from the secretary, T. Armstrong, 41, Moffat Road, Dumfries, N.B., on application.

MR. ALFRED WATKINS has accepted the presidency of the Photographic Convention for 1907. The Herefordshire Photographic Society have also held a preliminary committee meeting to consider things in general.

## Correspondence.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—It was my intention to allow this subject to drop, but after perusing the letter of your correspondent "Another Disgusted Assistant," in this week's issue, I feel constrained to put him right. For his edification I would point out that I am *not* a 4½d. per hour man. I am paid £90 per year as manager of a branch studio, and I have had experience in some of the best studios in England and Ireland. As I said in my last letter, this is not a *personal* grievance, but one which is felt by the whole body of photographic assistants. By assistants I mean all who are employed by others. There are many "amateur assistants," as well as "amateur professionals." These men are often advertised for. You see such announcements as "good amateur not objected to" in advertisements. These men I do not acknowledge. But there are many really good men employed as "general assistants" for a mere pittance, men who are capable of turning out good class work, yet who have no chance whatever of getting into better berths. General assistants they must remain. Why? Because they have not been employed by some big firm. Correspondingly there are many men holding places in good-class houses whose work is not so regularly good as many humble general assistants, but who can easily secure good prices because they can say, "I have been with So-and-so."

Take a general assistant in a country business as an example. I know several such. He has to turn his hand to anything, operating, retouching, printing in several processes, enlarging, copying, toning, etc., and he has to do all these in a place, and under difficulties, in which a first-class man would not be able to do anything.

He has no superabundance of apparatus and accessories, no conveniences for controlling the light, no big choice of backgrounds, only one or two lenses; often enough the apparatus is old and out of date. I know such a man. If he had the proper apparatus and accessories and good modern conveniences he could turn out work as good as many men getting £5 per week, but he has in his studio three chairs, a table, two backgrounds, and a rug. That is all the accessories he has to work with. He cannot control the lighting, there are no blinds or diffusing screens. He has no studio camera or stand, just a whole-plate field camera, with a half-plate anastigmat. The studio is too small for good work, being only 18ft. by 12ft. His dark-room is a box 4ft. by 3ft. Now would a man who is used to every modern convenience, all the latest apparatus, etc., do really good work under such circumstances? I am afraid not. Yet there are many "general assistants" who turn out passable work under these circumstances. Yet they cannot hope for anything better, because, forsooth, they have had no better experience. This is where the examination would put them on a level with others—give them a chance in the battle of life. Why cannot they be given this privilege? They are *men*, not animals, and as such can insist upon equal privileges as others. I am not pleading for incompetents; let them go, we do not want them.—Yours, etc.,

DISGUSTED ASSISTANT.

### FILM COLOUR FILTERS.

To the Editors.

Gentlemen,—Your "Ex Cathedra" notes this week contain a reference to the use of stained gelatine films for filters, which is of interest to me as an advocate of them some years ago. I believe it was in the JOURNAL ALMANAC for 1892 that I published a method of preparing them, and for some time I used gelatine films as filters, behind the lens. My experience was that, sooner or later, they invariably buckled, owing to their hygroscopic nature, and it was necessary to be constantly replacing them. I find nothing so satisfactory as glass. In landscape work one rarely needs more than one filter, and though at one time I carried four I now find the one

meets all requirements. This I have in a sliding panel, behind the lens, inside the camera, and it is always in position, so can be pushed to or fro to cover the lens or not as occasion demands. In another camera the filter is fitted into a sliding frame, working to and fro behind the lens, also inside the camera, but as the frame can be operated from the outside the filter can be pushed into position after the dark slide is inserted, or withdrawn if circumstances make it inadvisable to use the filter at the last moment. My filters weigh, with frame, under one ounce, so I do not think this is a serious addition in weight to one's kit. Of course, it is quite possible to use thin microscopic cover-glasses for filters, and they are most efficient, while their weight is little more than that of gelatine. I have recently made two filters for stereoscopic camera, with one-inch circles of thin cover glasses, cemented and mounted to fit on back of lenses, and they leave nothing to be desired.

Edwards, of course, issued long ago stained films, mounted for the diaphragm slot, and although the colour was excellent, better than any glass at that time procurable, I found them open to the objection of eventually getting out of shape. I am, yours faithfully,

G. T. HARRIS.

[Mr. Harris's note appears in the ALMANAC for 1903, p. 700.—Eds. B.J.]

### A NOTE ON THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—As a "Plate User" who finds a knowledge of the constants  $K$  and  $\gamma\infty$  of great practical use, I should like to add a few words to this discussion in the hope that it may help to clear up some of Mr. Payne's difficulties.

It is quite true that the constant  $K$  depends only on the ratio of  $\gamma_1$  and  $\gamma_2$  and may be the same for plates of very different qualities; but the constant  $\gamma\infty$  depends not only on the ratio  $\frac{\gamma_2}{\gamma_1}$  but also on the absolute value of the two development factors,  $\gamma_1$  and  $\gamma_2$ .

Thus, for example, test strips of two plates, A and B, developed for five and ten minutes give

Plate	$\gamma_1$ (5 minutes)	$\gamma_2$ (10 minutes)
A	0.8	1.12
B	1.5	2.1

In each case the ratio of the two development factors is equal to 1.4.

$$\begin{aligned} \text{that is } \frac{\gamma_2}{\gamma_1} &= \frac{1.12}{0.8} = 1.4 \\ \text{and } \frac{2.1}{1.5} &= 1.4. \end{aligned}$$

Referring now to Mees and Sheppard's table I. (*P. J.*, Nov., 1904), we find that this ratio corresponds to a  $K = 0.182$ ; which value is, of course, the same for both plates.

Now, however, to obtain  $\gamma\infty$  (the highest possible development factor), we must go to Table II. (*loc. cit.*) and, using the method there indicated, we find the values of  $(1-E^{-K})$  for 5 and 10 minutes to be

$$0.5972 \text{ and } 0.8379.$$

Dividing then the  $\gamma_1$  and  $\gamma_2$  of each plate by these figures we get

$$\begin{aligned} \text{for Plate A } \frac{0.8}{.5972} &= 1.3 = \gamma\infty \\ \frac{1.12}{.8379} &= 1.3 = \gamma\infty. \\ \text{and for Plate B } \frac{1.5}{.5972} &= 2.5 = \gamma\infty \\ \frac{2.1}{.8379} &= 2.5 = \gamma\infty. \end{aligned}$$

We thus see that the constants are

$$\begin{aligned} \text{for A } K &= 0.182 & \gamma\infty &= 1.3 \\ \text{for B } K &= 0.182 & \gamma\infty &= 2.5 \end{aligned}$$

It will thus be evident that though two plates giving very different values for  $\gamma_1$  and  $\gamma_2$  may have the same  $K$ , yet they will have different values for  $\gamma\infty$ , because this depends not only on  $K$ , but also on the actual magnitude of the  $\gamma_1$  and  $\gamma_2$  in each case.

The practical value of a knowledge of  $K$  and  $\gamma\infty$  to the plate consists in the fact that from these numbers he can calculate time required to reach any given development factor. Thus example:—An Imperial Orthochrom plate with a certain development at a certain temperature has the constants  $K = 0.163$  and  $\gamma\infty = 2$ . It is required to know how long it must be developed with the same developer and at the same temperature to obtain a development factor  $\gamma = 1.0$ .

Taking the equation

$$\gamma_1 = \gamma\infty (1-E^{-Kt})$$

and substituting the known values we have

$$1 = 2.15 (1-E^{-0.163t}),$$

from which the  $t$  required may be found as follows:—

$$\frac{1}{2.15} = (1-E^{-0.163t})$$

$$0.4186 = (1-E^{-0.163t})$$

From Table II. (*loc. cit.*) we get that this corresponds to a value  $Kt = .540$ , and dividing this by  $K = 0.163$  we get

$$\frac{.540}{.163} = 3.3 \text{ mins. (say 3 mins. 20 secs.)}$$

as the required time.

I hope the foregoing may be of some help to Mr. Payne and others in making clear the difficulties which are found in the study of the subject.—Yours, etc.

W. B. FERGUSON

Arosa, Suisse, July 20, 1906.

To the Editors.

Gentlemen,—I was glad to see Mr. Arthur Payne's letter, for had come across the same stumbling block in trying in my amateur way to understand and work the H. and D. system, as expounded by Messrs. Mees and Sheppard.

There is, however, one point upon which I should be glad to be still further enlightened, and that is whether the Hurter and Driffield constant of 34 still holds good with the acetylene light standardised to daylight. This was adopted for the standard candle, and I am under the impression that somewhere Messrs. Hurter and Driffield stated that if another source of light were used this would have to be altered.

Possibly Messrs. Mees and Sheppard can kindly enlighten us on this point.—Yours faithfully,

ARTHUR GASCOIGNE.

London, E.C.

### CLOUD PHOTOGRAPHY.

To the Editors.

Gentlemen,—I read with great interest "Some Notes on Cloud Photography" in your last week's issue of the B.J.P.

For some time past I have taken up cloud photography as a hobby, and find it intensely fascinating. I have also taken up the photography of lightning, of which I have several pictures, both of the multiple and single flashes.

Mr. Clayden suggests using a photo-mechanical plate for cloud work. I myself have tried these, but I found that they did not give sufficient tone value, but on the other hand they gave great contrast which is essential in showing the form of the cloud photographed.

About six months ago, I met with an announcement of a process plate that was also orthochromatic, viz., the Wellington Ortho Process plate; these I tried with great success. I found that even without a screen they gave excellent tone values, and in addition great contrast between the whites of the cloud and the clear sky. Although a pyro soda developer is recommended with the plates, I find for cloud work that a hydroquinone developer, such as that recommended for the "Mawson lantern plate," an excellent one.

I have suggested the use of these plates to several gentlemen engaged in meteorological research, who take a great interest in the work, and in each case they have expressed their approval.

With regard to the statements Mr. Clayden makes as regards the photography of lightning, he says, we should not hold the camera in the hand. I must say my procedure is a little different, but with a special aim.

July 27, 1908.]

I have, when taking photographs of lightning, no less than four cameras all working at the same time. Two I have fixed to a rigid support pointing towards different portions of the sky, and two more cameras, one in each hand, both of which are kept in a swinging motion from right to left. All four cameras are started exposing at the same time, and given a definite exposure according to the time of day or night I am exposing; a longer exposure may be allowed at night owing to less risk of fogging the plates. My reason for this procedure is, to try if possible to get a single flash on one plate, and multiple of the same flash on another.

Mr. Clayden suggests the use of fast plates for lightning, but does not say whether these should be of the orthochromatic type or not. I have found from experience that an orthochromatic special rapid is necessary. Some little time ago a storm passed over London, and, as usual, I exposed for the lightning, and although I was certain I saw several very distinct flashes in my view finder whilst exposing (the exposure, by the way, was not sufficiently long to fog the plates), yet upon developing the plates I found no trace of lightning upon them; the reason I attribute to the fact that the lightning was a distinctly non-actinic colour, and the plates not being orthochromatic.

We have our Societies for Survey Records, Architectural Work, and I see a Society is now on foot for Colour Photography. Why not a society for the Furtherance of Cloud and Lightning Photography, with an idea of helping meteorologists in their researches. Should be glad to become a member, if such a Society was started. Hoping I am not occupying too much of your valuable space and time.—Yours obediently,

HOWDEN WILKIE.

37, Engadine Street, Southfields, S.W.

## PROPOSED SOCIETY OF COLOUR PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I have been both gratified and encouraged by the friendly response and general interest which has been accorded to the proposal for the formation of a society of colour photographers, as set forth in my letter published in your issue of the 15th inst., and I take this opportunity of thanking all those who have written me in this connection, and who have sent in their names provisionally, as wishing to become members of the society. A meeting will be arranged to be held in London during the "Royal" exhibition, due notice of which will be given to those whose names I have then received. In the meantime I shall be glad to add to the list the names of both ladies and gentlemen who are working in colour photography, and shall be pleased also to receive any suggestions which may be helpful to the organisers, so that the society may be made to fulfil its purpose successfully.

Replying to the letter of "A Country Professional," I am glad to know that he is taking up colour work, and shall be happy to add his name to my list as a prospective member of the society. He does not sympathise with the suggestion that workers shall be divided into sections for the purpose of portfolio circulation; but I may assure him that he, as a beginner, will have no real cause to object to such an arrangement, for the society will, I hope, endeavour to encourage earnest workers in every possible way. May I remind him that success is nearly always built upon a foundation of failures, and that while one always admires perfect results, their very perfection covers up the methods by which such results were attained, so that all we can do is to admire. But with less perfect work before us, we may see, or have pointed out to us, the cause of failure, and thus acquire a knowledge which will be helpful to us in conducting future experiments in the same direction. This is particularly true of colour photography, and it is hoped that we shall have the co-operation of a few leading workers, who will not be influenced by professional jealousies, but whose first desire is to see this new phase of photography launched upon a successful career.—Again thanking you, in anticipation, I am, yours faithfully,

HENRY J. COMLEY,

Secretary, pro tem.

Surrey House, Stroud, Glos.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Weiss and Fowke, Victoria Road, Stafford. Two Photographs of the Hon. J. Chamberlain and Mrs. Chamberlain.  
G. Hynd, The Studio, High Street, King's Heath, near Birmingham. Photograph of J. Chamberlain, M.P.  
T. T. Hardwick, Ivy Gables, Rushford Park, Levenshulme, Lancashire. Photograph of W. G. Douglas and A. E. Noon in a Boat Displaying a Conger Eel caught by them at Port Erin.  
Walter Bellamy, 27, Hagley Road, Birmingham. Photograph of the Right Rev. the Lord Bishop of Manchester (Dr. Knize), size 12 in. by 10 in.  
Fred Nainby, Photographer, Challenger Street, Cockermouth. Photograph of Sir John Randles with Foot on Step of Motor Car.  
Louis G. Carpenter, 88, High Street, Ramsgate. Four Photographs of the Ramsgate Pierrots.  
Thomas Albert Scotton, 1, 165, London Road, Alveston, Derby. Photograph of King Edward, on his Way to Royal Agricultural Show at Derby, June 28, 1906.  
Payne & Cuddy, 12, Shop Street, Drogheda. Photograph of Dunleer taken from Tower of Church.

ENLARGEMENT.—Is it possible to make an enlargement from a negative so that the picture or enlargement would be 20ft long?—C. HUNT.

It is, of course, possible to make an enlargement 20ft. long, but a great deal depends upon the negative in the first instance. If the negative were a 10 x 8 then the enlargement would be twenty times, and assuming the so-called critical definition existed—that is to say, the diameter of the disc of confusion did not exceed one two-hundred-and-fiftieth of an inch, it is obvious that with this enlargement the fuzziness would be clearly visible, unless the enlargement were examined from a considerable distance. Theoretically, of course, there is no limit to the enlargement.

A. E. N.—Your print is what is known as a cameo, and is made in the ordinary way, then put into a cameo press, which gives it the cushion or raised up shape, and it is then backed with cotton wool or paper, and mounted by the edges only.

THOS. RILEY.—Certainly, any number less than six are admissible.

E. R. LEWIS.—Three or four houses, at the most. Hood and Co., St. Bride Works, Middlesbrough, or Carl Hentschel, Limited, Fleet Street, or Hamel and Co., Premier Studios, Palmerston Street, Nottingham.

DONE.—The lady certainly cannot claim compensation, nor can she in any way stop publication, provided the print does not libel her. The following extract from the ALMANAC for 1906, where will be found a very useful summary of the law of copyright, puts the facts very clearly:—"Can a photographer display or publish prints from negatives he may take of persons or places? It seems hardly necessary to put the question, for the above clause of the Act clearly states that no one has the right to forbid the representation of any scene or object. If there is any restriction, it falls under common law without reference to copyright. A photograph of Alderman Jones, J.P., obtained in the street of Blankton, without his knowledge, is the photographer's to use as he pleases, and Alderman Jones cannot prevent him so long as the display of the photograph does not transgress the law of libel, by exposing the subject, for example, to such notice or ridicule as may prejudice his commercial, social, or official position. Similarly I may photograph the residence of Alderman Jones, and he cannot prevent my using the view as a postcard, though he may put forward the existence of the postcard as proof that on a certain occasion I trespassed on his estate. It is questionable if he could make much of such a case, but the general position

remains unchallenged—viz., that so far as copyright is concerned, the photographer has the right to photograph anything "photographable, and to sell or exhibit his copies."

**S. R. SHARP.**—You cannot possibly have a great depth of focus with a lens working at F. 4. Still, the only lens which answers to your other requirements is the Zeiss Planar, No. 12, which covers a half-plate at F. 4.

**P.O.P.**—Some months back you had a series of articles on P.O.P. printing and toning in the *BRITISH JOURNAL*. I have mislaid the number. Will you please give the toning bath formula, which was recommended not to give double toning? If I recollect there is no sulphate of potassium used. I have been used to using the albumenised paper, and find great difficulty in getting certain results with the P.O.P. By using the combined bath I find the prints tone too quickly to be fixed properly if left in, the vignettes turn yellow at edges and give poor prints.—**ALBUM.**

The articles appeared in our issues for July 7 and 14, 1905. Three formulae are there given, as preferable to the sulphocyanide bath. Sodium phosphate, 24 grains; chloride of gold, 1 grain; distilled water, 20 ounces. This must be mixed just before use, and it is important to use distilled water. The second bath is: Sodium formate, 15 grains; sodium carbonate, 2 grains; chloride of gold, 1 grain; distilled water, 20 ounces. This must also be mixed just before use. The third formula is the one specially recommended, and it will keep well in the dark as a stock solution. 1. Thiocarbamide, 30 grains; distilled water,  $\frac{3}{4}$  ounces. 2. Gold chloride, 15 grains; distilled water, 4 ounces. To the latter add sufficient No. 1. to redissolve the precipitate first formed the quantity required will be about two ounces. Then add: Citric acid, 30 grains; salt,  $\frac{1}{4}$  ounces, and enough distilled water to make  $7\frac{1}{2}$  fluid ounces in all. Every half ounce of this solution will contain one grain of gold, and may be diluted with water for use. With regard to the combined bath, no formula is given, so we are unable to tell the exact cause of the trouble; it may be due to excess of gold, absence of chloride, or insufficiency of hypo.

**CASTLETON, KIRBY.**—Your retouching is of very poor quality, but what can you expect after only working at it for such a period as stated in your letter. Your work presents no solidity, gradation, or modelling, and the necessary texture is entirely absent. The best advice we can give you is for you to at once place yourself in the hands of an expert teacher, and have proper lessons, either personal or postal, instead of trying to teach yourself—always an unwise and hopeless task.

**COPYRIGHT QUERY.**—I am publishing a number of local views as postcards, and wish to make them copyright. There will be a couple of dozen or more of them, and to make them copyright singly will cost more than I care to pay. Can I, if I mount them in eights on a board, copyright them as one picture?—**ECONOMY.**

No; to secure the copyright each picture must be registered separately.

**LENS QUERY.**—I have a studio 16ft. long and 9ft. wide. What portrait lens should I get? I shall want to take full-length cartes and cabinets, groups, and also large cabinet heads.—**J. WITHERS.**

The lens you ask for has not yet been made. A lens of 6in. focus requires about 13ft. distance for a full-length carte picture, but this will not cover the cabinet size. One of 10in. focus requires 14ft. for a cabinet, but this in the space you have will not take a full-length carte, so that you had better have at least two lenses. A third with a still longer focus would be better for the large heads, as with that you will get more pleasing perspective than with the 10in. one.

**LENS.**—I have a whole-plate portrait lens, bearing the name of Bourquin offered me cheap. Will you please say if he is a good maker.

Bourquin was not a maker of lenses. He was a photographic dealer carrying on business in London many years ago. The lens, no doubt, is of French make, and may be a very good one. But we should advise you to test it before purchasing.

**FACTORIES ACT.**—I shall be greatly obliged if you would reply to the following inquiry in your "Answers to Correspondents"

column: Do my photographic premises, studio, etc., come under the Factories Act? I employ one male operator (age 22) studio, one male operator outdoors (age 21); also, one young lady apprentice (age 22), and one young lady in shop taking orders (age 20). The inspector tells me that the girls are allowed to work only from 8 a.m. to 3 p.m., and must be home one evening off at 4 p.m. each week.—**ABER.**

We should say that your business comes within the Factories Act, and you will not be able to work the girls longer than from 8 till 8, with suitable hours off for meals. Surely this is long enough hours for young people to work. They must also have a half-holiday each week, as well as all Bank Holiday.

**A GRIEVANCE?**—A few weeks ago I photographed a lady's child and submitted untuned proofs in due course, which were paid for at the time of sitting, but which were not approved. I was therefore, somewhat surprised a week ago to see exhibited in a local photographer's window a whole-plate enlargement of my carte de visite portrait—presumably taken from one of my proofs. I have written the lady to request the photographer to remove from his window what is obviously not his work, however good, bad, or indifferent it may be; but the enlargement has not yet been removed. The photographer himself has not yet approached. I believe I have no redress. (1) Is this so, or not? (2) If so, what would you recommend me to do?—**RENE.**

1. You have no remedy, and why should you have? You have been paid for taking the portrait, and the one who paid for it has, clearly, the right to do as she likes with it. If she likes to have an enlargement of the portrait shown in another photographer's window you cannot prevent. 2. You can do nothing.

**VALUE OF BUSINESS.**—I would be glad if you could give me a little information as regards the value of a business which I am compelled to sell owing to ill-health. My business brings in between £400 and £500 a year, and I reckon the profits at about £250 to £300. The class of work I do is considered middle-class, and the population is what is called a floating one—always changing. My rent and rates are £40, and I have a lease of eighteen years to run. The average rent of other shops in the same street is £65. I would be glad if you could give me a little information on this.—**SURREY.**

It is without our province to value photographic businesses, as so much must necessarily depend upon local conditions, the prices charged, the cost of labour, the amount of opposition, and so many other things. If you consult the advertisement columns of the *Journal* which are devoted to businesses for sale you will doubtless be able to form some idea as to what yours is worth in the market.

**GERMAN DUTY ON PLATES.**—Can you inform me if the duty on photographic plates (unexposed) taken to Germany is very excessive. I propose taking a holiday in Germany, and would like to take plates with me, if the duty is not too heavy.—**C. E. FOWKE.**

The duty is about 30s. per cwt., but, as a rule, if the plates are only taken for personal use, and not for sale, there is not any trouble with the Customs. Many English plate-makers have agents in Germany.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographers' and assistants' agreements should be based on the principles of equity, and not be so wide as to become invalid. (P. 603.)

The preparation, cutting, staining, and mounting of specimens for photomicrographic work opens up an extremely interesting field for photographers, which forms a welcome relief from everyday work. (P. 604.)

Translucent and opaque head screens frequently obviate the necessity of shifting the blinds in the studio. (P. 602.)

M. Goderus tilts a strong lance against the generally accepted axiom that the images in the stereoscope are superimposed. The effects obtained he ascribes simply to mental impressions. (P. 606.)

The action of ink on P.O.P., and a method of photographing burnt documents, and a new dodge for invisible writing. (P. 608.)

An able criticism from an artist's point of view of Herr Dührkoop's work—which was recently on exhibition in our offices—suggests also how photographs and pictures should be looked at. (P. 608.)

Mr. Herbert Ives's improvements in the diffraction process of colour photography render this process much simpler and more practical. (P. 609.)

A patent which gives photographically the effect of the old slat advertisement, which showed different wording according to the angle it was viewed. (P. 613.)

An important case of implied contract, which is likely to carry considerable weight in commercial dealings, was fought in the Court of Chancery this week. (P. 615.)

Japine platinotype comes out most satisfactorily under tests. (P. 614.)

The question of assistants' certificates still attracts attention, but this week a disgusted employer has something to say on the other side. (P. 617.)

## EX CATHEDRA.

### Lens Panels.

One of the minor worries of the photographer who wishes to use or test various lenses is the provision of lens panels. Very seldom does he find two different lenses that will fit the same flange, or two different flanges that will fit the same panel, and the provision of a new panel is often necessary. For temporary purposes a millboard panel will serve, though one built up of several thicknesses of thin card, glued or pasted together and allowed to dry under pressure, is somewhat better. A wood panel is best for permanent use, and thin mahogany fret-wood is perhaps the most desirable material. If millboard or card is used there is generally some difficulty in fixing the flange with ordinary screws, and it is usually most convenient to screw the lens direct into a hole cut in the card, and so dispense with the flange altogether. Cutting the hole is, however, not the least of the difficulties, and it is one that has to be surmounted whatever material is employed. The camera maker generally cuts it in a lathe, but if a lathe is not available we have to fall back on more primitive methods. A centre-bit is of course most effective, but a centre-bit of the right size is seldom available, while the expensive variety known as adjustable centre bits are very little use. They require a lot of power when set to cut large openings, will not feed themselves through thin wood unless it is backed by something much thicker, and, worst of all, generally split the panel. The fret saw is tedious and unsatisfactory, as it is by no means easy to saw a perfectly circular hole, and hammer and chisel is slow and produces a rough hole that requires a lot of after-trimming. For a long time, however, we have used hammer and small chisel as the best of these several methods, and only quite recently have we hit upon a better method that is equal to the lathe in point of effectiveness and superior in the matter of time. We now use an ordinary washer cutter. This is a brace tool, costing 1s. 9d., and intended for cutting holes or complete washers in leather. If the knife is kept sharp it works perfectly in thin wood or in millboard, and produces a clean hole of any diameter up to five inches, with a very few turns of the brace. The hole is a bevelled one, and if it is bored from the back of the panel the bevel is just the kind required for a wood panel. But if the lens is to be screwed directly into a card panel the hole should be bored from the front, as the bevel then assists the screw in biting into the edge of the board. It may be noted that panels made of thin card, glued together, and dried under heavy pressure can be sawn, cut, sandpapered, and even rebated in just the same way as wood. They will not take a wood screw well, but if rebated panels are required and wood is not available, the built-up material is far superior to millboard.

### Film Negatives In Studio Work.

So far the film has not supplanted the glass plate for studio work, and indeed the advantages of a firm support for the negative image are numerous. It is for example much easier to retouch a glass plate negative than one on a film. Still, we think many of the advantages of glass are more imaginary than real; the convenience in handling, for instance, being rather a question of use. Film negatives might be varnished more rapidly than glass plate negatives, and, of course, the freedom from risk of breakage is an important point. In one respect, however, the film negatives scores unmistakably. It offers the most convenient method of making carbon prints, the single transfer process being employed, printing through the film, while at the same time the negative is equally available for the platinum or other processes for which its contrast and gradation might be suitable. Films may now be obtained at a cost very slightly in advance of that of plates, and in such a form that they may be employed in the ordinary dark slide. In making experimental negatives on cut films we have found one of the difficulties is to keep the films sufficiently flat and in the proper plane. The depth of a wide aperture portrait lens is so slight that any buckling of the film is quite sufficient to cause out of focus areas. By pressing it forwards against a sheet of thin patent plate glass perfect flatness would be ensured, but a slight increase of exposure would be necessary, as there would be a loss of light through reflection and absorption, and, of course, one of the slides would need altering slightly, so that the sensitive surface occupied the same plane as the ground glass.

### The Head Screen In Lighting.

Those portrait operators who have not used an ordinary head-screen, covered with tracing cloth or butter muslin, as an aid to lighting head and shoulders of half-length pictures, have not yet found out to what an extent they may save the time and trouble hitherto spent on manipulating the roller or curtain blinds of the studio. Not only is the saving of trouble considerable, but the end gained is greater, for nothing is more distressing to the sensitive sitter than a lot of noise and bother in making alterations of blinds or furniture, and if by simply placing the head-rest in various positions the necessary modifications can be made in the lighting, the sitter is unconsciously grateful and the expression is correspondingly improved. If two head-screens are at hand, one covered with a very diaphanous material, and the other with something comparatively opaque, say brown holland, it should be possible to arrange almost any lighting without touching the blinds, assuming that they have been previously placed in a normal position, and that the type of sitter is not very abnormal. The diaphanous screen may be placed between the head and the skylight, and will soften the lighting to almost any degree, the nearer the head the screen is placed the softer and more delicate the illumination. By removing this screen altogether and placing the more opaque one over the head, the shadow side may be made darker, and so the contrast of light and shade apparently increased. One great advantage of lighting in this way is that the raising of dust by moving the blinds is largely avoided during the time the sitter is in the studio.

### Implied Contracts.

The report of the case of *Doff v. Sachs*, which appears elsewhere, is somewhat interesting, and we think is of some importance, too. Briefly, a photographer is commissioned by a firm of postcard publishers to photograph a certain number of members of the theatrical profession, and at the same time takes the opportunity to secure a series of negatives for his

own use. An action by the postcard publishers to stop publication of these photographs fails; the defendant wins the day with costs. Whether the photographer is to be congratulated must be purely a matter of personal opinion, but there is no question that this decision, if not upheld on appeal, may considerably militate against the profession generally. It is a case of sufficient importance to be widely reported, and no doubt the attention of other postcard publishers will be specially directed to it, with the result that photographers may in the future have to submit to more stringent contracts in accepting orders for this class of work, or lose it altogether. Nor does the decision affect only this work; it must apply to all orders, for Mr. Justice Warrington's decision means that an order implies no contract to execute this and this only. The decision opens up innumerable possibilities of trouble. There is no parallel apparently between this and the *Crooke-Irving* case, for in the latter special permission was accorded by Sir Henry Irving for extra sittings, although the original sitting was for a third party.

### An Epidemic of Fading.

We have received during the last week or two a large number of prints, chiefly postcards, on P.O.P., which all seem to suffer from the same trouble, namely, more or less distinct evidences of partial fading. These marks are in nearly all cases accompanied by that peculiar coloration, or discoloration, of the image which is characteristic of sulphuration. In several cases we have been at some pains to find out the method of working, and apparently the procedure has been to tone with bath which have been allowed to stand for some time to ripen or else have been made with hot water and then used while cool. The fixing bath has, however, been used freshly made. On further inquiry it was found that toning took place fairly rapidly, and that it was assumed that fixing would be also accelerated. Working precisely on these lines, we found experimentally that a toning bath made up and allowed to stand for twenty-four hours was exactly ten degrees above the fixing bath. The obvious lesson to be learnt is that the fixing bath, when freshly made and consequently cooled down, should be given time to do its work thoroughly, and so that the comparatively insoluble hyposulphites of silver may be dissolved.

### The Washing of Postcards.

There is one point which frequently seems to be forgotten by postcard users, and that is their thickness. The result of this is that the washing in between and after operations is by no means so thoroughly performed as it should be. A very ready test on this point can be made by faintly printing a P.O.P. card, bromising in the usual way, and then developing with an alkaline developer and immersing in a gold bath. It is really astonishing how long one may wash and yet obtain the characteristic purple tint on the back due to the precipitation of metallic gold. If an experiment be carried out on these lines, and the card be subsequently split, which is by no means a difficult matter, it will be found that the interior layers are distinctly tinged, even although the outer surface is quite free from any purple tint. The thickness of the card conduces to this result, and one has also, of course, the somewhat impermeable baryta coating, and then on that the gelatine of the emulsion.

### The End of The Picture Season.

The picture season, so far as auction sales of the finest works are concerned, is now over. It has been a notable one for the exceedingly low prices that pictures of the Academy type have realised at sales; in some cases less than a quar-

the sum they sold for a few years ago. It is also noteworthy by reason of the exceedingly light prices at which works by some of the old masters changed hands. Perhaps the most notable thing in connection with the past season's sales is the extraordinary high prices that have been given for old engravings, in some instances much more than for well known paintings by leading R.A.'s. As an example of this we may mention that a couple of months ago, at Christie's auction rooms, an impression of Walker's plate of Mr. Masters, after Romney, fetched £30, while the week before, at the same sale rooms, F. Odhams' well known picture the "Raising the Maypole" was sold for only 400 guineas. In 1873 this same picture sold 1,470 guineas. Last week, at the same rooms, a fine etching of J. R. Smith's "Lady Caroline Montague as a child" was knocked down for no less a sum than £700. The past picture season has served well to illustrate the great fluctuations there are from time to time in the picture market.

\* \* \*

#### Fogging Under-Exposed Prints.

It is difficult to understand why there is a greater tendency for an under-exposed or an unexposed plate to fog than for one which has had the normal full exposure. Yet that such is the case we have noticed over and over again, and no doubt every observer who has experienced the same thing. It might be argued that an unexposed plate fogged through undue exposure to the light of the developing room, or that in some way it had been fogged in the camera by stray light. But it is quite possible to take suitable precautions to avoid either stray light or unsafe dark-room light and still observe the phenomenon. We have developed six or eight quarter-plates exposed in a hand camera, placing them all in one dish, applying the developer and covering the dish. A plate accidentally unexposed or taken fresh from the plate-box and placed amongst the exposures will, after the expiration of five minutes' development, usually show a fairly thick veil of fog, while the whole of the exposed plates may have produced negatives quite clean and bright. It has been suggested that this fogging only occurs with plates which have a predisposition to fog, but we have noticed it with clean working plates of moderate speed. A somewhat similar phenomenon has also been brought to our notice recently in the case of testing emulsions by the Hurter and Driffield system. A series of strips when developed with the standard pyro developer and a distinctly high fog reading, but plates coated with the same emulsion exposed in the camera were as clean and as brilliant as could be wished.

\* \* \*

#### Enamelled P.O.P.

For certain classes of work the enamelled-surfaced print will always be in demand. Not only in portraiture, but where the detail is required in some kinds of technical work the glossy bromide or the enamelled P.O.P. answer the requirements admirably. Twenty years ago this class of print was produced by enamelling the albumenised paper print with collodion, a piece of patent plate glass being French-chalked and coated with thin enamel collodion, in contact with which, under a warm solution of gelatine, the albumen print was placed, the excess of gelatine being squeezed off. The modern enamelled P.O.P. print is simply produced by squeezing to a chalked glass or a ferrotype plate. The albumen print if backed with a fine quality of waterproof paper attached with an adhesive not likely to become acid was protected from the deleterious action of the air on both sides, and its chances of permanence

increased. The collodion surface was to a great extent waterproof, or at all events, any chance splash of water might be wiped off and a moist finger would not injure the surface. The gelatine surface of the P.O.P. is exceedingly liable to injury from moisture, and it is difficult to satisfactorily enamel such prints with collodion. We have found that if the print is simply laid down on the collodion as it comes from the wash water there is a certain amount of risk of the film of collodion peeling partially after the print is dry. This risk is increased if the prints have been through a hardening bath of either alum or formaline. The only reliable method seems to be to thoroughly formaline the prints after toning, fixing, and washing, so as to render them insoluble in a hot gelatine solution, and to treat them as the albumenised paper prints were treated. Even then it is somewhat doubtful if the adhesion of print and collodion film is as perfect as it is with albumen, which is of a more porous nature than a tanned gelatine film.

#### PHOTOGRAPHERS' AND ASSISTANTS' AGREEMENTS.

EMPLOYERS when engaging assistants, particularly if they have to take an important position in the business—say, as manager of a branch, for example—very frequently make it a condition of employment that the employee signs an agreement that when he leaves the service he will not commence business for himself, or enter the service of another photographer, within a certain radius of the place of business. Such agreements usually stipulate that in the event of the employee breaking this part of it, he is to forfeit to his late employer a certain sum of money by way of damages. This is but fair, if the agreement is an equitable one, as the employer is justified in protecting his interests. If, say, an operator-manager were put, we will imagine, to manage a branch business, and, after he had well established himself with the customers and the district, were to start a business on his own account, or, perhaps, enter the services of a competing photographer, it is possible that it might work considerable injury to the late employer's trade. Such agreements are reasonable enough, supposing they are framed in a reasonable way; but sometimes they are not.

Not infrequently they are drawn out by the employer himself, and are made far too arbitrary, and too far-reaching. In some instances the employee, being very anxious to obtain an appointment, does not very carefully read and digest the conditions imposed; or they may not be clearly understood by him at the time of signing. Hence he does not fully realise the restriction imposed until, perhaps, some disagreement arises. Then he finds himself in an unpleasant position. Copies of some of these agreements have, at times, been sent us for perusal and to have our opinion thereon, and we can say that some of them have been of a most unreasonable character, as they bind the servant in an inordinate manner. Now, an agreement must be equitable on both sides, for it is one of the maxims of equity that he who would have equity must first practise equity to the other party.

We will here quote a case to show that agreements may be made that are too exacting, and thus become void in law. It was tried quite recently in the Lancaster County Court. Incidentally we may here mention that County Courts have jurisdiction in equity where the sum in dispute does not exceed five hundred pounds. Briefly the case was this. A firm of drapers and house furnishers in Lancaster sought an injunction against a former manager from carrying on business with his wife, he having signed

an agreement not to enter into the service of any person or firm, or to enter into any business in opposition to his late employers, within a radius of ten miles of Lancaster. In the event of his doing so he agreed to forfeit a year's salary, £120. The defendant is now carrying on business with his wife as a draper within a couple of hundred yards of his late employer's shop. The defence was that the defendant was his wife's manager, and that the agreement was void because it was too wide, being in restraint of trade, and against public policy. The judge held that the covenant was greater than was necessary to protect the plaintiff's interests, and that the agreement was invalid and could not be enforced. We have quoted this case to show that agreements for services may be framed too wide and so become invalid, and when that is the case a late servant, if he commences even in close proximity to the premises of his late employer, cannot be restrained because the agreement made is not a valid one.

The question which now arises is what is a reasonable restriction? That must necessarily depend, to a large extent, upon circumstances. If, for example, a man signs an agreement not to commence business on his own account, or enter the service of another in, say, a small town of perhaps six to ten thousand inhabitants, or a couple of miles round it, the conditions would be very different from those obtaining in a large town, say London. In the former case it could not be considered an undue restriction of trade, but in the latter it certainly would, and such an agreement would be invalid and could not be enforced. In the copy of an agreement, submitted to us some time ago, the operator was prohibited from following his profession in three adjoining counties, and, as there was no time limit mentioned, it endured for all time.

Such an agreement, though duly stamped, as this was, obviously invalid on the face of it, as it was undoubtedly an undue restriction of trade, and purported to prevent the employee from getting his living within far too wide an area.

The object here is to point out to employers that framing agreements with servants when engaging them if they make the stipulations too wide they cannot force them, and thus they defeat the object they have in view. In all such agreements there should be a time limit mentioned, as, for instance, say, a year from the time the employee leaving the service, otherwise it might be read that it was for ever, and that might possibly be sufficient to invalidate the agreement. The employer's interests, as a rule, would be sufficiently protected if a photographic employee were prohibited from setting up business within a year or so of the time of his leaving, by that time he would be almost forgotten by the majority of the customers. We venture to say that there are many photographers' agreements in existence at the present time that could not be enforced in a court of law owing to their inequitable nature. As just said, agreements must be equitable to both parties. If, for instance, an operator were engaged at a weekly wage, and signs an agreement to start business, etc., while at the same time he is liable to be discharged at a week's notice, such an agreement is not an equitable one, as it is all one-sided. If the engagement were for a definite term, say for one or more years, it would be more in accord with the terms of equity inasmuch as the servant would be secured employment for the term agreed upon, unless he were discharged through some fault of his own, such as misconduct or neglect of duty.

## HOW TO PREPARE AND PHOTO-MICROGRAPH BOTANICAL SPECIMENS.

To gain experience in the manipulation of his apparatus, and at the same time become familiar with the preparation of microscopical material, the would-be photomicrographer cannot do better than turn his attention to the study of plant life. The vegetable kingdom will supply him with examples of the simplest as well as the most highly developed forms of structure, all requiring careful examination and consideration, forming most suitable subjects for photomicrography. Specimens of the *phanerogamia*, the flowering and seed-bearing plants, are always near at hand, and afford a never-ending source of interest to the photomicrographer, yielding him a rich store of beautiful and easily prepared objects.

To thoroughly grasp the importance and uses of the microscopical structure of the plant, it is necessary to become familiar with its life history, to seek it growing in its natural environment, and there observe the parts that the various organs of the plant—the stem, roots, branches, foliage and floral leaves, and seed—have to play in the battle of life. The photomicrographer should, when out collecting material, carry a camera with him, that he may photograph the plant growing in its natural environment, for such photographs will help him to realise the why and wherefore of the specialisation of the microscopical structure of the plant.

The apparatus required for mounting and preparing botanical specimens for photomicrography need not be very elaborate or expensive. For cutting the sections of stems, etc., a good razor and some form of microtome will be required, together with a supply of paraffin wax, pith, or carrot, for embedding the object in the "well" of the microtome.

Methylated spirit will be wanted for hardening and fixing purposes; and for perfectly bleaching the material preparatory to staining, the following bleaching bath:—

Dry chloride of lime ...	...	...	2 oz.
Common washing soda ...	...	...	4 oz.
Distilled water ...	...	...	2 pints.

Mix the lime in one pint of water, and the soda in the other. When the soda has dissolved mix the two solutions together, shake well, and let it stand away from the light for twenty-four hours. Filter the clear fluid, and keep it in a glass stoppered bottle in a dark place.

A useful collection of stains for general purposes are:—Acid aniline green, borax carmine, eosin, hæmatoxylin (logwood), methyl aniline, and rosaniline violet.

According to the nature of the specimens, and the manner in which they have been prepared, so they may be mounted in either Canada balsam, Deane's medium, or Farrant's medium—the last two being particularly useful for delicate cellular tissues. Should the tissue be very soft in texture it may, with advantage, be allowed to soak for a day or two in the following bath before it is mounted in Deane's medium:—

Pure glycerine ...	...	...	2½ drachms.
Rectified spirit ...	...	...	5 drachms.
Distilled water ...	...	...	5 drachms.

When the soaking has been completed, the specimen is drained and mounted.

All specimens to be mounted in Canada balsam must first be thoroughly freed from every trace of moisture (dehydrated),

which is best accomplished by soaking in several changes of methylated spirit and absolute alcohol. The freshly-gathered leaves, stems, roots, etc., of species of the phanerogamia intended for cutting into sections, staining, and mounting in Canada balsam, should be cut into moderately small pieces, and placed in a glass jar containing a liberal supply of methylated spirit, which must be changed regularly every day until no colour comes away, when the specimens will be ready for further treat-

then wash in methylated spirit. Next remove the section to a bath consisting of one part hydrochloric acid to twenty parts methylated spirit, in which it should remain until bright scarlet in colour and any excess of stain has been removed, after which wash in clear methylated spirit. The section is now placed for ten or twenty minutes in the alcoholic solution of aniline green, after which it is well washed in methylated spirit, and if over stained soaked in it. The specimen is then dehydrated in methy-

ment. Although soaking in methylated spirit dissolves out most of the colouring matter, a large proportion of the specimens will require further bleaching ere they can be properly stained. Such specimens must be soaked in changes of distilled water until freed from all trace of spirit, and then placed in the bleaching bath already described. Bleaching successfully accomplished, the specimens should be washed in water until no trace or smell of chlorine remains, when, after a final wash in distilled water, they will be ready for staining.

Paraffin wax is, for most purposes, a more satisfactory imbedding medium than pith or carrot. Take 8oz. of pure paraffin wax, and 2oz. of lard, and with the aid of gentle heat melt them together. Half fill the well of the microtome with this mixture, and insert in it, in the desired position, the specimen for cutting into sections, and then fill up with more of the melted wax mixture. When the wax has cooled and set firm, the sections can be cut, the superfluous wax clinging to them being got rid of by immersion in turpentine, or oil of cloves.

Young stems, and ovaries that do not contain much woody tissue, stain well with hæmatoxylin, after they have been properly bleached and cut into sections, and form most interesting and beautiful subjects for photomicrography. To stain, take 30 drops of solution of hæmatoxylin and add one ounce of distilled water. In this dilute stain immerse the sections for ten or twenty minutes, until the required depth of colour has been obtained. Then wash the section in distilled water, and then in ordinary tap water until the colour becomes blue. Place the section in strong methylated spirit for at least fifteen minutes, then into absolute alcohol to thoroughly dehydrate; place it in oil of cloves for ten minutes to clear, wash in turpentine, and mount in Canada balsam.

The most effective photomicrographs of sections of roots, stems, ovaries, and leaves, will be obtained by double staining the specimens. The following I have found give very good results:—Dissolve two grains of Grüber's aniline green in one ounce of methylated spirit. Place the section to be double stained first in a watch-glassful of borax carmine for six to eight minutes;

luted spirit and absolute alcohol, cleared in oil of cloves, rinsed in turpentine, and mounted in Canada balsam.

Eosin and hæmatoxylin double stain sections of roots, stems, and ovaries finely. The section is first stained with hæmatoxylin, and then placed for a few moments into a dilute solution of acetic acid and distilled water. It is then washed

Transverse section of stem of pine showing one  
year's growth ×10. Example of double staining.

thoroughly in several changes of distilled water, to remove every trace of acid, after which it is placed in ordinary tap water for eight or ten minutes. Now place the section in a 1 per cent. solution of eosin in alcohol for five or six minutes, wash well in methylated spirit, dehydrate in alcohol, clean in

oil of cloves, rinse in turpentine, and mount in Canada balsam. Sections of the stem of the vegetable-marrows should be stained with eosin to show the sieve tubes and plates. For differentiating sections of stems of monocotyledons, resaniline violet gives beautiful results. It is composed of equal parts of methyl-violet and fuchsia (magenta), mixed and dissolved in alcohol. It is a useful stain to show up the stratifications of cell walls, etc.

Supposing that we have successfully prepared our sections, let us next consider how we can obtain the most satisfactory and truthful photographic rendering of them. Backed orthochromatic plates must always be used, and I would strongly advise factorial development with pyro-soda minus potass bromide, as giving the ideal photographic negative—clear, bright, with long scale of gradation. The pyro-soda formula I use has a factor of 12; that is to say, supposing the image takes thirty seconds to just appear, development is then continued for six minutes—the dish being covered with a piece of board during the whole operation. An orthochromatic screen is certainly desirable if fairly true colour rendering is aimed at. Personally I prefer a moderately deep one, about a 10 or 12 times, but the depth of screen must be governed by the brand of plate employed.

A very great deal of the ultimate success of the photomicro-

graph depends upon the careful selection of the most typical and perfect section and to the selection of suitable magnification. In all branches of photomicrography there is one correct magnification for each subject, and a magnification above or below that will not produce such a perfect or pleasing picture; therefore, it is very important to gravely consider and decide the magnification the subject is to receive, and in this practice and experience are the best teachers. As some rough guide to the tyro the following list of magnifications may be helpful. Stems and ovaries to show good appearance from 10 to 30 diameters. To show cambium layer in transverse section, 40 to 50 diameters. To show an isolated vascular bundle in a transverse section of the stem of *Zea mais*, a magnification of 250 diameters will generally give the best result; while to isolate a sieve plate in the vascular bundle of cucumber stem 412 diameters will give a fine picture, showing the minute perforations of the plate. The various cell contents require between 250 and 500 diameters.

Working in the field with the camera, and at home with camera wedded to microscope, the photomicrographer will find the study of plant life and the record of its many wonders, by the aid of photography, a most fascinating hobby that will keep him busy at all seasons of the year.

F. MARTIN-DUNCAN.

## THE INTERNATIONAL CONGRESS OF PHOTOGRAPHY.

Almost unknown in the United Kingdom, the International Congress of Photography is a body which obtains a large share of recognition on the Continent, where its meetings have hitherto taken place. In aim distinctly scientific, the Congress may claim to have reduced any human passion for notoriety which it may have possessed in its early days, for its proceedings gain publicity in the press after a time, which is incomprehensible in these days of hurry, not only in the lay press, but in circles which are avowedly sectional or scientific in their province. Hence it is that the full report of the Congress, which met in July, 1905, in Liège, only came into our hands a few weeks ago. We had obtained access to a partial account of the session from one or two of the Continental journals, and an article in our issue of March 2 last gave certain recommendations of the Congress in reference to standards in plate speeds, colour sensitiveness, and other photographic values. Now, however, we may reprint two of the papers read in July of last year—viz., one on "The Superposition of Stereoscopic Images," by M. A. Goderus, and one on certain points in photography applied to criminology, by Dr. Reiss, of Lausanne. In doing so we may express the hope that the executive of the Congress will wake to the fact that their procrastinatory methods appear inexorable. A reasonable delay in the publication of papers purporting to be of scientific value is naturally an evil which is readily overlooked, but we imagine that any reading public will expect to see in print the deliberations of a midsummer congress at any rate before New Year's Day.

### The Superposition of Stereoscopic Images.

In all general treatises on photography, in works on physics, in dictionaries, and in special treatises on stereoscopy, even the most recent, we are taught that the illusion of relief is produced by the superposition of two stereoscopic images, either by the aid of an arrangement of mirrors, by prisms, or by lenses, which act as convergent prisms, as their centres are further apart than the pupils of the eyes. It is said looking thus through the margins of the lenses they act as prisms, and cause the stereoscopic images to deviate one to the other so as produce superposition.

The classic figure which one finds everywhere is the following:—It is said that the eyes *OO* looking each at one of the stereoscopic prints *AB*, *A'B'*, and the superposition is effected by the lenses or prisms in *A'B'*.

This is an absolute error, which has obtained such a hold of men's minds that it has induced the superposition of material images, or

when the two images are printed in red and blue, and viewed through red and blue spectacles.

The merest common sense tells us, however, that to see the exact reproduction of nature in the stereoscope it is necessary that the eyes should look in this instrument as they do in nature. A single example will show us how little the theory criticised will realise this desideratum. When we look at a spire of a tower which just emerges on the horizon, the visual rays are practically parallel. It cannot be sustained that there is convergence towards the tower, because visual

FIG. 1.

convergence supposes the application of attention to a point situated relatively near the eyes, and which cannot be applied to a surface larger than the separation of the eyes, which is 6.5 cm. Supposing our tower on the horizon is stereoscopically photographed, and supposing that the two prints are printed one on top of the other in blue and red, and looked at with a pair of blue and red eye-glasses, the tower will be represented as a sort of pencil-point about 30 centimetres from the eyes, upon which the optic axes will converge, instead of remaining parallel as in nature. We shall not, then, see the stereoscopic effect as it is seen in nature, because the axes converge instead of remaining parallel.

One may object, however, that the illusion is perfect. I reply that this statement is too absolute, and that one only believes that one sees the relief as it is in nature, for want of having the model at one's side to judge of the difference of perspective. No one can believe the relief to be true if, instead of printing the images in red and blue one on top of the other, they are printed side by side, or so that one partially covers the other, but in such a manner that the image of the tower in the right picture is separated 6.5 cm. from that in the

picture. In looking then at the tower through blue and red glasses, the optic axes will remain parallel, as in nature, and one will have the exact perception of real relief, if the two images are placed at such a distance from the eyes as to occupy the same angle on the retina as the image occupied in nature. To obtain this result, it is usual to employ lenses which enlarge the images, for these are made with lenses of short focus, and cannot be seen at the convenient distance except by myopic eyes. A diagram will enable us to comprehend more easily the logical truth of our thesis.

Fig. 2.

The dimensions of this printed page will not permit us to represent a distinct landscape and parallel vision. Let us take an interior AB in which the axes OP, O'P converge to a point P, the face of a clock, for instance. It is well known that a design, a picture, a photograph, is that in which one has applied perspective in one plane; that is to say, the right eye O sees the subject AB as if all the subjects were drawn on a transparent glass placed at ab or cd. It will be seen that the angle AOB occupied by the subject remains the same, at whatever distance the projection of the image is produced. The left eye, seeing the clock face P, sees the picture as though drawn at a'b' or c'd'. It will be immediately seen that two images, which are supposed to be projected at ab and a'b', are not superimposed at all, but just side by side as the stereoscopic images, and that the images pp' of the clock should not be superimposed, but should be on the straight lines op, op', which converges, like the axes of the eyes, towards the point P.

The largest dimension possible of the stereoscopic photograph of the interior should be ab', and the separation ought to be pp', that is to say, slightly less than the separation of the eyes, seeing that we are imagining an interior AB not far off, and in which the convergence of the optical axes is obvious. If the point P represented a tower on the horizon of a landscape, the visual rays would become parallel, and the separation pp' should be equal to that of the eyes of the observer, but it ought never to be more according to theory.

As the images ab, a'b' are placed too near our eyes to be seen, they are enlarged by means of the lenses LL, and then the virtual images cd, c'd' are seen partially superimposed from c' to d, and then the images p<sup>11</sup>, p<sup>111</sup> of the clock are slightly nearer than pp', in such a manner as always to be found on the straight lines OP O'P. We project then the two images p<sup>11</sup> p<sup>111</sup> in P, where they are superimposed in our minds, as though actually situated in P.

We ought not to forget that when we look into a stereoscope, we do not see one or two images, but really the illusion of reality, and that this illusion causes the superposition of the images of different objects in their respective planes. In fact, two stereoscopic images cannot be superimposed, because they are different from each other. If they are mounted so that the points on the horizon are separated by 6.5cm., the exact distance, the drawing of the objects in the foreground planes are less separated than the eyes looking at the foreground planes ought to converge to see them distinctly.

Let us start the parenthesis to satisfy the curiosity of those who may ask why the stereoscopic prints ought to be mounted in the inverse order of the negative, that is to say why the right-hand print should be placed to the left and vice versa. Here we have a poor

explanation, which is found in all books. It is evident that the right-eye O ought to see the image ab, as the left eye O' ought to see the image a'b'.

But how is this to be arrived at in photographing AB by the aid of two lenses placed at OO', and having a focus equal to op? We have to produce beyond OO', two negatives of the subject AB, in which the objects will be found with the top at the bottom and the legs in the air. As one must print a double image before placing it in ab' for seeing it, it is necessary to reverse each of the two stereoscopic images to present them reversed from top to bottom. This cannot be done without separating the one from the other and reversing each in its turn. That means mounting the left print on the right, and vice versa; but this is not the same thing. Actually the print produced by the lens at O ought to be viewed by the eye placed at the same point O, and reciprocally the print produced by the left lens O' ought to be viewed by the left eye at O'; and to mount on the right the print of the left means making the prints take a half-turn about their centres to inverse the reversal produced by the lens. Mounting the right-hand print on the left is a dodge which completely fogs the comprehension of the mechanism of stereoscopy, for this leads one to believe that the left eye sees the right hand print, and vice versa, which is absurd.

Let us now see what is the origin of this false idea of the superposition of the pictures by means of prisms or other subterfuges.

1. It has been proved that the play of the accommodation muscles of the eye and the mental superposition of the pictures are sufficiently elastic to permit us to go beyond the limits which ought to be traced by nature. 2. It has also been remarked that we may increase the angle AOB, that is to say, see, stereoscopically, a larger quantity of the horizon in ab, a'b', if the lenses OO' are separated rather more than the normal distance of the eyes, and this is why our stereoscopic cameras have a separation of 7.5 cm. instead of 6.5 cm., which ought to be the normal. But, then, the pictures should also be separated by 7.5 cm. from centre to centre, and they should not then be seen with divergent vision, that is to say, not by squinting. Some people attain this result by exercise, and it is less difficult than one would believe after the first trial. But it is useless to make these efforts because one can place between the eyes and the pictures two prisms, conveniently placed. These do not cause superposition of the images, but merely provoke a slight deviation towards the centres, just as though they were only separated by 6.5 cm. or slightly less if the foreground planes are considered. 3. As objects are seen in the stereoscope as one, it has been concluded that the two images were superimposed, as in our first diagram. It has been entirely forgotten that in the stereoscope we do not see more than the pictures, but that in our brains the illusion which they produce of the same objects exists, not on one plane, but in three dimensions in their respective planes.

FIG. 3.

The perfect superposition of images by means of prisms is impossible, for the image of a square, deviated by a prism, becomes a trapeze, and the two trapezes, which ought to superpose, having an inversely symmetrical form, cannot combine, for the small side of the one falls in the large side of the other, and the other two sides cross one another, as shown in the figure.

If the half-lenses forming convergent prisms, which are used in stereoscopes of the better class, are to cause superposition of the pictures, it is necessary to look through the thin part of the glass, where the effect of prismatic deviation is strongest. If it is said, on the other hand, that the thin edges of these instruments are in contact and the pictures are viewed through the thick parts of the lenses, the effect with all good stereoscopes is merely that the centres

of the achromatic lenses enlarge the images, and that they impinge the one on the other, as in  $cd^1d^1$  of the second figures; but the two images  $p^{11}$   $11'$  of the clock P are not superimposed. The brain,

when directing the vision in the two directions OP, O<sup>1</sup>P, perceives by the aid of the two images,  $p^{11}$   $p^{11'}$ , not superimposed, an illusion of one reality P situated in P.

A GODFREY

## SOME PROBLEMS OF JUDICIAL PHOTOGRAPHY.

M. Bertillon was the first to point out that when certain inks were used for writing and that when the paper, as soon as the characters were dry, was pressed into contact with another sheet of paper, there was produced on the latter an invisible impression which could be rendered visible by heat. Later, I completed the work and found that the effect was produced by the acid in the ink acting on the sizing, and that neutral and basic inks did not act in the same way.

Experiments were made to find a method of reproducing the invisible image without in any way damaging the documents. The paper which was suspected to contain the invisible image was pressed into close contact with a piece of P.O.P. and left in contact in the dark for from six to twelve hours. The sensitive paper was then exposed to light till it was blackened, and the writing was then clearly legible in metallic characters on a dark ground.

The defect of this method was that the characters were faint and could not be easily photographed, so another method was tried. The papers were pressed into contact as before, then the P.O.P. was exposed till the ground turned a reddish violet and then physically developed. The ground blackens, but the characters gradually appear with a metallic sheen and development should be continued till they are quite legible. The developer used was a 1 per cent. solution of pyro plus 10 per cent. of glacial acetic acid. To obtain black proofs on a white ground it is only necessary to place the back of the P.O.P. in contact with the paper containing the invisible characters.

### Photographing Burnt Documents Written in Pencil.

The burnt document should be fixed on a flat piece of wood in a dark room and placed in front of the lens at an angle of about 30 deg. It should then be illuminated by a powerful incandescent gas lamp so that the light falls on the document at an angle about 80 deg. The lamp should be placed at the end of the box which is furthest from the lens. If now the image is examined the ground glass the writing will be seen as luminous, though faint lines. On the negative the characters will appear black on a grey ground. It is necessary, of course, to use a yellow sensitive plate and from the position of the document very small diaphragms must be used, and hence follows a very long exposure. In the position the writing will appear in white on a dark ground. This method of great value.

### Invisible Writing on a Black Ground.

There are several commercial picture postcards which bear the pictures of old masters surrounded by a black frame. Recently a case was met with in which a criminal had used this black frame on which to write a message to his accomplice. As a matter of fact if this black frame is written on with black ink, the writing completely disappears when dry and passes through the post without comment. To decipher the message I gave the card a coating of water colour varnish, and the writing immediately became visible and could be easily photographed.

R. A. REISS.

## HERR DÜHRKOOP'S WORK.

The following is a brief synopsis of a lecture given by Mr. John Fisher, Hon. A.R.C.A., London, upon Herr Dührkoop's collection of portraits before the Bristol Photographic Club:—

Mr. Fisher commenced by saying that the standard set by the pictures was so high as to be quite bewildering. In fact, he thought that to a true artist their effect would be almost discouraging for that very reason, but that to a true student their effect would be highly encouraging and stimulating, on account of the possibilities they revealed. The standard of artistic quality in some of the portraits was such that much careful study was required in order to properly appreciate them. In hastily glancing round an exhibition it is often the case that the best pictures do not assert themselves so forcibly as some of the others. Generally those which produce the greatest impression at the first glance are what may be termed "Almanac" pictures, or pictures which would make a good advertisement.

In examining a collection of pictures it is necessary first of all to dismiss from the mind those which are either aimless or too attractive, and then to approach the remainder analytically. Ask yourself the questions—Why does it please or displease me? What does it mean? Do I understand it? Don't condemn immediately. Stand before a doubtful picture until its meaning and the intention of the artist begin to dawn upon you.

Herr Dührkoop's work showed that he was a cultured artist, a man who went straight to Nature in her simplest form, and who was quite independent of accessories, or rather a man who knew exactly what accessories were required, and how much they required to be emphasised or subdued. Indeed, Herr Dührkoop impresses the beholder with the purposeful nature of all the objects he includes in his portraits.

The only way in which a student can acquire a knowledge of art is by constant association with what is acknowledged to be good

in the pictorial world, and it was readily apparent that Herr Dührkoop had studied and been influenced by the paintings of some of the world's greatest artists. In portrait work it was essential to study the inner character as well as the outer characteristics of the sitter. Your sitter has some special interest; find it out and introduce a secondary object into your picture suggestive of it, and, if possible, discover yet another interest to form a tertiary object in your picture. The study of good work by good artists will enable the student of art to understand what is meant by this association of primary, secondary, and tertiary interests in a picture, and the great value of this combination from a pictorial point of view.

To become an artist (photographic or otherwise) the student must, firstly, "Learn to see"; secondly, "Learn to memorise"; and thirdly, "Learn to produce." These three stages must be passed through in the above order, otherwise the student's work will never reach a high level.

These remarks are well illustrated by Herr Dührkoop's work, for he is such a thorough master of the means at his disposal (lighting, tone-value, composition, and technique), as well as an artist, that his pictures are full of poetical feeling, raising them to the level of real works of art.

The correctness of his tone-values give, in some of his examples, a wonderful suggestion of the natural colours of the objects portrayed. Sharpness or fuzziness in a pictorial photograph were immaterial, provided that it had correct tone values, suggested colour, and gave relief to the object taken.

Dührkoop in his prints obtained very pronounced light and shade effects without the least harshness, and in many cases the extreme high light on a collar or cuff was the making of a picture. His scenes were all ordinary every-day scenes, but carried out with consummate ease, grace, and naturalness, and while he always obtained

the artistic effect he wanted, he at the same time always retained truth to Nature. This is the only satisfactory way, for where the artistic effect is produced by violating truth, then the lie surely comes home to roost, spoiling all pleasure in that picture.

Mr. Fisher thought that the members would greatly benefit by working on the following lines. Let the club obtain a copy of "The Hundred Best Pictures," exhibit a certain number of them at one of the club meetings, and let members vote as to which picture appeals with the strongest interest to them. Then let each member prepare a print based upon the chosen picture (that is, a print expressing the same sentiment in a similar way, but not being a

slavish copy of the original), and then send all the prints into the Folio on a certain date, or exhibit them at a club meeting.

In this way all those participating would learn much in respect to lighting, composition, tone-values, and sentiment. A smaller number of photographs might result, but the use of mind in their production would be stimulated.

In portrait work the operator is often a victim, for he may have ideas, but be unable to carry them out owing to lack of sympathy in the model. Therefore photographers were advised to search persistently until they found a sympathetic model, and when found to cultivate him (or her), for a model in harmony with the operator will go a long way towards making a real picture.

## IMPROVEMENTS IN THE DIFFRACTION PROCESS OF COLOUR PHOTOGRAPHY.

(A paper read before the Franklin Institute, Philadelphia.)

The diffraction process of colour photography, invented by Professor R. W. Wood, of John Hopkins University, in 1899, is an application of the well-known three-colour method of reproducing colours by photography. This method depends primarily upon the observations of Young, Helmholtz, and Clerk Maxwell, that all the colours of the solar spectrum may be counterfeited to the eye by mixtures of three narrow bands of colour from the spectrum. These colours are red, near the Fraunhofer line C; green, near E; and blue, near F. For instance, red and green mix to give the eye a sensation of yellow indistinguishable from the true yellow of the spectrum; red and blue mix to give purple; and the three colours acting together produce a white whose difference from ordinary white light can be detected only by analysis with a spectroscope. What applies to spectrum colours applies equally well to the varied hues of nature. The colouring of such an object as a basket of fruit can also be duplicated to the eye by mixtures of the three primary colours. The tint of an apple, by a large proportion of red, less of green and blue; of a lemon, by nearly equal parts of red and green; of grapes, by a large proportion of blue.

The three-colour process can be reduced to two problems; first, the production of three photographic negatives, each of which shall be an exact record of the amount of one of the primary colours requisite to mix with the others and counterfeit to the eye the colour of the object photographed; second, some means of furnishing each record with its appropriate colour and combining it with the others.

The solution of the first problem has been arrived at from experimental quantitative determinations of the mixing proportions of the primaries to produce the other colours. From these determinations three-colour screens can be prepared, which, when used with suitable photographic plates, will yield three (black and white) negatives, each having the desired destitution of light and shade to form a record of one primary colour. The negatives thus obtained are the basis of all three-colour reproduction methods.

Numerous means have been suggested and tried for combining the three-colour records with their corresponding colours. They may be placed in a triple lantern, each illuminated with its proper coloured light and projected, superposed, upon a screen. The superposition may be effected by a system of mirrors, as in the Kromskop; but the use of three thin transparent films properly coloured; by triple printing on paper, after the manner of much of the present-day magazine illustration.

A process which must be noted somewhat in detail because of its direct bearing on the recent development in diffraction colour photography is the so-called Joly process.\* Combination of the colours is effected in this by breaking up the three-colour records into narrow lines, arranged in succession, a line of the red record, a line of the green, a line of the blue, and so on, repeating across the picture. This triple record, whose lines should be close enough together to be indistinguishable by the eye, is mounted over a triple ruled colour-screen—a line of red pigment, a line of green, a line of blue, similarly

spaced to the lines of the picture. The result, if the lines are fine enough—a condition never yet attained in the actual working of the process—is that the eye blends the lines to form a structureless colour picture in the form of a transparency.

The diffraction process, which is the subject of this paper, departs widely from the other methods. Its distinguishing feature is that for the production of the primary colours to view the records use is made of the diffraction grating, that is, of a transparent polished surface, usually of glass, ruled with fine parallel straight lines, several thousand to the inch. It is the property of a diffraction grating that if a bright line or point of light is viewed through it, not only will the light source be seen, but spread out to either side will be a series of spectra, those nearest the source being called spectra of the first order, the next, of the second order, etc. If the number of lines to the inch on the grating be increased the spectra are thrown farther from the central image, and vice versa.

The power of a grating to produce colour is taken advantage of in the following way: Suppose we have a convex lens forming an image on a screen of a bright source of light, such as a gas flame. If the eye is placed where the image is formed the lens is seen uniformly and brilliantly illuminated. Suppose now a diffraction grating is placed over the lens. In addition to the image formed as before there will be produced a series of spectra. If the eye is placed in one of these the lens will, as before, appear illuminated, not, however, by light of the colour of the source, but by the colour of light striking the eye.

If now we can make one of our colour records in the form of a diffraction grating of varying strength to correspond to the desired differences in the amount of the primary colour, and place it over a

lens, points can be found in the lateral spectra in which the lens (and the grating in coincidence with it) will appear as a coloured picture. Further, since, as we have seen above, the distance of the spectra from the central image depends upon the fineness of the grating spacing, it is a simple matter to choose three gratings, one of which will send red to a chosen point, the second green, the third blue. Hence if we can make the three primary colour records in the form of three diffraction gratings of three properly chosen spacings,

\* First published, as a matter of fact, by Louis Ducos du Hauron in 1869.

each may be seen in its proper colour by placing the eye in one of the diffraction spectra formed as above described.

In Fig. 1 we have represented the conditions for viewing diffraction colour pictures. A is a source of light, B a convex lens, in front of which are three gratings G. On the screen D fall the central image I, and three spectra (only the first order spectra on one side are represented) so placed that the red of one, the blue of another, and the green of the third are superposed on the slit S, at which the eye is placed.

In Fig. 2 we have represented diagrammatically a diffraction colour picture of a red flower with green leaves on a blue ground. The coarse spacing of the lines in the flower represents a grating to send red light to the eye, say 2,400 lines to the inch, the medium spacing of the leaf one to send green to the eye, say 3,000 lines to the inch, the fine spacing of the background one to send blue, say 3,600 lines to the inch. Mixed colours would be given by two or three gratings acting together.

To produce such gratings by photographic means the bichromated gelatine process, which lends itself well to the copying of minute structures, was used. In contact with a surface sensitised in this way was placed a glass grating; the image of the corresponding colour record was then projected upon the surface for a sufficient time to

FIG. 2.

give a full exposure. The grating was removed, another substituted and exposed under its corresponding colour record, and so with the third. In this way all three grating pictures were printed, one on top of another,\* forming a picture which by diffused light was transparent and quite invisible, showing its colour only when viewed with the proper combination of lens and bright source of light. From the pictures made in this way copies could be made by simple contact printing on bichromated gelatine. Since a direct copy of a grating is still a grating, i.e., a series of lines, the process is a positive one and copies are not reversed in light and shade as in making copies of ordinary photographs.

It is obvious that quite apart from its scientific interest the diffraction process promises very real advantages. For instance, the colours used are beyond question pure spectrum colours, and so there is no need to depend on dyes or coloured glasses; also the ease and cheapness with which copies can be made places it in a class by itself among three-colour processes. So perfect indeed did the process seem theoretically when first published that there was every reason to expect results fully comparable with the best of other methods.

This early promise was not fulfilled. A few pictures were obtained, interesting as scientific curiosities only. No dependence could be placed in the results; some colours reproduced well, others did not; occasionally a good picture would be made, but the same procedure applied to another subject brought no success. Six years after its publication the process had made no progress and seemed fated to rank as a failure.

Last summer, through the courtesy of Professor Wood, the writer was lent a number of diffraction gratings, ruled on the Rowland dividing engines at Johns Hopkins University. Experiments with these revealed a fundamental defect in the above-described mode of making diffraction pictures. By finding means to overcome this defect results have been obtained of a remarkable degree of perfection.

The defect referred to is that the three gratings, in order to get their joint effect, were superposed, being, as we have seen, printed one on the other. In so doing the assumption was made that the

effect of superposing gratings was to add their separate effects. A matter of fact, additional disturbing effects are introduced, partly due to the inability of the gelatine surface to take several gratings impressions without mutual blotting out, and partly—chiefly, in fact—to the forming of a new compound grating. That is, if two gratings of different spacings are superposed, the two spacing periodicities get in and out of step with each other, and this new periodic structure forms itself a diffraction grating. The new grating then forms its own series of spectra, which subtract light from the original one. Therefore when the two gratings are superposed, the eye, instead of receiving a double quantity of light, receives much less than the double quantity. Even more serious than this loss of light is the fact that the new spectra due to the two gratings together frequently fall in such a position as to introduce false colours. This is well illustrated by taking two gratings of different spacing and placing them on one another at right angles. Two sets of spectra will be formed, one by each grating, and parallel to it, and, in addition, a number of diagonally disposed spectra. As the gratings are turned into the same straight line all the spectra turn, and the additional diagonally placed spectra take up positions between the spectra formed by the original gratings. Consequently, while the eye may receive red from one grating and blue from another, one of the spectra due to the two together may send some other colour, such as green. This case actually occurred frequently, a pink rose reproducing as green, and red and blue colour discs superposing to give green instead of purple.

These observations made clear the necessity for some method of obtaining the effects of the three gratings other than by superposition. It was at once seen that this could be accomplished by a procedure similar to the Joly process, namely, by having the grating elements in narrow juxtaposed strips. Some experiments had already been made by Professor Wood with Joly pictures, not, however, with the specific purpose above mentioned, but rather to illustrate the possibility of making such pictures with very much finer colour lines than it is possible to do by ruling alternating coloured pigment lines to the observing screen. The mode of procedure involved laboriously ruling a special grating consisting of several lines of one spacing, followed by several of another, and then several of the third, repeating all the way across the plate. The width of each strip of lines was made to correspond to the width of an element of the Joly picture. From this grating a print was made on the special-line picture, which had been previously flowed with gelatine. This in turn was used to print gelatine copies.

A practical disadvantage of this plan, aside from the use of the special grating, is that one is restricted to the use of original Joly pictures of a certain definite spacing of line, determined by the limitations of the process employed in their production. A much more serious defect arises, however, in this way: The "Joly lines," if made, as they should be made, several hundred to the inch, themselves form a diffraction grating, which, as it is parallel to the three principal gratings, forms spectra superposed on those depended on to reproduce the colours of the object. This is quite as serious a defect as that arising from superposed gratings, and is sufficient to condemn the procedure.

FIG. 3.

From a consideration of these various difficulties it followed that some means of breaking the picture up into lines was imperative, and that that means should not involve the use of a special grating, nor of special Joly original pictures, difficult to obtain, and, most important of all, the narrow colour strips or Joly lines must be arranged in some way so as not to give disturbing grating effects.

All of these ends were achieved by the following procedure:

In Fig. 3, which represents the method of making the improved diffraction pictures, A is the bichromated gelatine plate, rigidly

\* In practice it was found impossible to get three impressions on one gelatine surface, and so two were made on one surface and the third on another, the two surfaces being afterwards placed in contact.

in position; B is a glass diffraction grating; C is a line screen, with at least two hundred lines to the inch, with the opaque lines twice the width of the transparent;\* D a lens, and E a positive four-record to be copied. The latter is an ordinary three-colour negative containing no lines or structure,† and the grating is an ordinary continuously-ruled one. With, say, the red record at E, and a corresponding grating at B, an exposure is made, resulting in a series of narrow strips. A second positive is then placed at E, the corresponding grating at B, and the ruling C moved the width of a transparent portion. A second exposure is then made, the opaque lines shielding the previously exposed surface, and a similar treatment given to the third positive. There results finally a picture made of alternating strips of three different gratings.

To eliminate the grating effects of the narrow strips of gratings considered as lines, the device is used of making the strips (Joly lines) at a right angles to the diffraction grating lines, so that the spectra produced by them are thrown off in another direction and do not enter the eye. Although the device is simple it is of extreme importance, and its adoption is rendered possible only by the plan described for making the pictures. The difficulties in the way of using a special grating with the three gratings disposed in a similar manner are practically insuperable. It is obvious that the strips of grating can be made as narrow as desired, easily narrow enough to be indistinguishable as such by the eye.

Fig. 4 gives an idea of the appearance of the finished picture under

FIG. 4.

a microscope. The short, fine lines are the diffraction grating lines furnishing the three primary colours; 2,400 to the inch for the red, 3,000 for the green, and 3,600 for the blue. The broad strips at right angles to the grating lines constitute the "Joly lines," which there should be at least 200 groups of three to the inch.

When viewed with a lens and bright source of light the pictures made in this way are entirely free from the formerly-obtained defects. The colours are pure and brilliant, and, unlike ordinary Joly pictures, the colours lines are too fine to be visible. The results, indeed, approach those obtained with the Kromskop.

As a further modification of the original method the writer has found it possible to dispense with three gratings and obtain the colours with a single grating spacing properly used. To do this the source of light must be a rather long slit. Viewed through a grating the slit, of course, gives long spectra parallel to its length. If now the grating be rotated about, the perpendicular dropped from it to the slit, the spectra move in toward the slit. [The accompanying diagram shows the slit parallel to the length of the slit is compensated for by the slit being long.] So, by suitable rotation any desired spectrum colour may be obtained at a chosen point. Starting with a grating of 3,600 lines to the inch to give the blue when parallel to the slit, a rotation of about  $21\frac{1}{2}$  degrees will give the green, of 42 degrees the red. In the absence of suitable dividing engines to rule three properly-proportioned gratings this affords an exact and easy method of securing the three colours. It has the fourth advantage, that in printing copies such difficulties as securing perfect printing contact will affect all three colours alike, which is not the case with gratings of different degrees of fineness.

\* The opaque line screens were ruled by Mr. Max Levy, to whom, for his interest and generous assistance, the writer is greatly indebted.  
Positives from negatives made for the Kromskop were used.

Fig. 5 shows a portion of a picture made in this way with one grating spacing.\*

With these improvements probably the last word has been said on the diffraction pictures themselves. A very important improvement

FIG. 5.

in the means for observing them, due to the writer's father, Mr. Frederic E. Ives, must be described.

The lens and bright light used by Professor Wood do not form at all a convenient arrangement, nor is it desirable to use artificial light. A convenient apparatus, easily set up, not liable to get out of order, and suitable for daylight use, became desirable as soon as the pictures are perfected. The instrument about to be described

was devised a few hours after the first pictures were obtained, and admirably fulfils its purpose. The greatest difficulty attending the use of daylight is that of getting sufficient light—the illumination of the sky, toward which an instrument would naturally be pointed, is far from intense enough. This will be appreciated when it is remembered that only a very small portion of the original light is diffracted, perhaps ten per cent. at most. This difficulty has been overcome in a novel manner. Instead of depending on a single slit, as the narrow source of light, a series of slits is used, each furnishing one spectrum. In this way, with four slits, two first order and two second order spectra are utilized, yielding probably three times the light obtainable from a single slit.

Fig. 6 gives the instrument in section. A, B, C, D are the four slits; M a mirror; L<sub>1</sub> and L<sub>2</sub> lenses; P the diffraction picture; and S the slit through which the picture is observed. The lenses, of course, form an image of each slit at A<sup>1</sup>, B<sup>1</sup>, C<sup>1</sup>, D<sup>1</sup>; from each of these images, however, a certain amount of light is diffracted by the picture P; from B and C first order spectra fall on S, from A and D, second order. The use of second as well as first order spectra is a distinct advantage in that, as gratings never give a perfectly uniform distribution of light and colour, certain desirable qualities of the picture are found in one order and not in the other, while if both orders are used the resultant evening up of qualities produces particularly satisfactory results.

By disposing the grating lines in a horizontal direction and using

\* After working out this idea the writer learned that some years ago Mr. Thorp of Manchester, suggested the use of a single grating spacing to secure all three colours. Mr. Thorp's plan, however, was to use three sources of light and merely rotate the gratings until they "found" the source and each cleared the source belonging to the other two. He found a rotation of ten degrees convenient. As far as the writer knows this is the first publication of a plan to secure any desired colour by rotation through a definite angle to be calculated from the wave length.

horizontal slits as sources the pictures may be viewed by both eyes, a desirable condition for convenience and comfort.

As an instrument the "Diffraction Chromoscope" is simplicity itself. It is, in fact, used much as the old stereoscope.

There are no adjustments; to use, it is merely placed before a window or Welsbach light and the pictures dropped to place. On looking into the eye slit before the introduction of the picture nothing

FIG. 6.

is seen, the inside being perfectly black. The pictures themselves are transparent, colourless, and appear as plain pieces of glass under ordinary conditions of illumination. On placing them in the instrument the colours immediately flash out, a transformation which seems almost magical, affording a scientific demonstration of rare beauty.

Aside from the obvious use of the apparatus for scientific purposes it is expected that its simplicity and the perfection of the results will ultimately lead to many important uses. Now that the long standing obstacles in the way of success have been removed the process should develop rapidly. Such further steps as application to lantern projection and means for making the pictures directly in the camera are under consideration.

HERBERT E. IVES.

## Photo-Mechanical Notes.

### Moiré Effects.

Russ, of Munich, has been examining the moiré effects obtained by the superposition of cross-line blocks in three-colour work, and gives the following figures in explanation. Fig. 1 shows the effect of two cross-lined screens, in which  $a\ b$  and  $a'\ b'$  are the dots of two

Fig. 1.

colours,  $c\ d$  and  $c'\ d'$ , the former being marked with crossed lines and the latter with horizontal lines. Rosettes and stars enclosed in larger squares are formed; if one of the inks is pale this will not be very troublesome, but if both are rich in colour, then the pattern will be very distinct.

Fig. 2 shows the effect of dots crossing one another at an angle of about 15 degrees. The dots then arrange themselves small squares, enclosed in larger ones, with the corners cut off. In this figure it will be seen that the dots arrange themselves into leaving considerable intervening spaces of white paper without dots, so that the effect is the same as though a much coarser screen had been used. When three blocks are used, incorrect posi-

Fig. 2.

the cross-lined screens will always give rise to the most striking moiré effects, and particularly those with broad banded effects. Generally, too, it will then be found that yellow ink partially lies between the superimposed dots, which the black moiré effects, with the result that yellowish and green tints are formed. Frequently, too, some of the red is superimposed on the yellow, and this gives rise to brownish bands. In order to avoid these effects the dots must be so arranged that the colours are evenly distributed over the smallest spaces, and it was soon found that an angle of 30 degrees was the best with three cross-lined screens. Then very small star effects are produced, which are not so irritating. The stars immediately disappear if, instead of a cross-lined screen, a single line be used, an effect which is aimed at when a line screen is used with a cross-lined screen. The angle of the lines may then be 60 degrees. This effect is not possible with a line stop and cross-lined screen without great loss of detail, and only very fine

Fig. 3.

originals can be thus reproduced. Line-screen blocks are much more difficult to etch than cross-line, and care should be taken to arrange the stops that the dots are rhomboids and strung together like pearls on a string, and this effect should be carried as far as possible without loss of sharpness. This pearl string formation is easy to etch, and gives a much quieter effect. When the cross-lined screen is used the etcher or fine etcher must be very careful in etching the blue and red plates, or the line formation will be lost. When the lines are superimposed over cross-line screens a fine moiré is also formed, as will be seen from Fig. 3; although the direction of the lines  $a\ c$  forms an angle of 30 degrees with the dots  $a\ c$ , and brighter and darker zones are formed. These are best seen when the figure is examined in the direction  $b\ c$ . It will be seen that the distance is double that of the original distance.

### PHOTO-MECHANICAL PATENTS.

PHOTO-MECHANICAL PRINTING.—No. 23,990. 1905. This invention is a process of photographically preparing two metal rollers of

plates for combined mechanical printing, which comprises the following transactions in combination: making two counterpart sheets, each of which is partly transparent and partly opaque; making two counterpart developed gelatine plates, with those counterpart sheets, respectively; applying ink to the depressed surfaces of those two plates; transferring ink from those depressed surfaces, respectively, to the respective surfaces of two metal rollers or plates; and etching away the naked surfaces of those two metal rollers or plates. A solution of gelatine is mixed with ammonium bichromate and alcohol, which is poured upon matt celluloid, fastened with fish-glue to a steel plate, and then dried by heat and again coated and dried. This is then printed on and immersed first in warm, and then in cold, water; an image is thus obtained in relief, which may be hardened with chrome alum. The celluloid bearing the image is then stripped from the steel plate, and a mixture of glycerine, citric acid, potassium nitrate, and chrome alum applied, and after removing excess of moisture the plate is inked up with an ink composed of asphalt, rosin, beeswax, mastic mutton tallow, and commercial crayon ink. A copper roller is passed over the inked surface and the fatty ink is transferred to the same. An enamelling powder of rosin and shellac is applied and melted by heat, so as to form a resist for the etching solution. The claim is for the process of photographically preparing two metal rollers or plates, for combined mechanical printing, which comprises the following transactions in combination: making two counterpart sheets, each of which is partly transparent and partly opaque; making two counterpart developed gelatine plates, with those counterpart sheets, respectively; applying ink to the depressed surfaces of those two plates; transferring ink from those depressed surfaces, respectively, to the respective surfaces of two metal rollers or plates; and etching away the naked surfaces of those two metal rollers or plates. Henry Lewis Reckard, 101, Beekman Street, New York, U.S.A.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes."*

The following applications for Patents were made between July 6 and 21:—

**MAGAZINE CAMERAS.**—No. 16,148. Improvements in magazine photographic cameras. Walter James Gilchrist and Johns, Son, and Watts, Ltd., 73, Cheapside, London.

**CAMERAS.**—No. 16,198. Improvements in and relating to cameras. Charles Edmund Peczenik and Augustus John Gratte Maskens, 27, Chancery Lane, London.

**CAMERAS.**—No. 16,253. Improvements in and relating to photographic cameras. Octave Edouard Jules Joublin, 27, Chancery Lane, London.

**PHOTO-PRINTER.**—No. 76,390. A continuous non-slipping photo-printer. Harry Harry Vickers, Finsbury Square Buildings, London.

**RAPID PRINTING APPARATUS.**—No. 16,507. Photographic apparatus for rapid printing of midgets and other photos. Alfred Gabriel Tooth and John William Riley, 4, Hillingdon Mansions, Elephant Castle Hotel, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PRINTING FRAMES.**—No. 20,563. 1905. This invention relates to an ordinary printing frame, provided with a window of glass or other transparent or semi-transparent material, part of which is obscured, and with a negative carrier, by the shifting of which, relative to the obscured window, various selected portions of a picture can be printed in varied shapes without the necessity of masks or change of printing frame. The claim is for the

combination of a rectangular mask having a rectangular window space or opening at one end or side thereof, suitable to the size of the photographic negative to be printed from, coupled with a rectangular negative carrier of the same size as the before-mentioned mask, with an opening cut at one end or side thereof, suitable to the size of the window space or opening in the mask. Ernest Christopher Elderton, 137, Osbaldestone Road, Stoke Newington, Middlesex.

**PHOTOGRAPHIC PRINTING.**—No. 91, 1906. This invention relates to the production and display on what seems to be to the casual observer the same surface, of two photographic views, either one of which can be brought into view at the will of the observer. To effect this, a sheet of photographic printing paper is fastened by means of shellac and alcohol, or other adhesive insoluble in water to a sheet of cardboard. The cardboard, with the paper attached, is then passed between two rollers, one of which is smooth and the other cut into sharp, parallel corrugations, either lengthwise or around the

Fig. 1.

circumference of the roll, so that the sensitive paper comes into contact with the roller having the corrugations. This operation leaves the paper upon the card in the shape illustrated by Fig. 1. The corrugated paper so prepared is placed in contact with a photographic negative in the ordinary manner in a printing frame. It is then placed in a receptacle impervious to light, except for an aperture at one side, through which the rays of light approach, and meet the corrugated printing paper, attacking and printing the same only on the sides of the many corrugations which face towards the aperture from

Fig. 2.

which the light comes. This negative is then removed, and against the paper is placed a second negative in the same manner. Now shift the printing frame so that upon exposure the light will meet the other and opposite sides of the corrugations in the paper, and in this manner the second picture is printed upon the sides of the corrugations opposite to those already exposed and printed. After the exposure, the fixing and toning of the photograph or two photographs is done in the usual way. Both pictures being on the same sheet, they are toned, fixed, and developed at the same time. The above description refers to the use of the invention for producing upon the same sheet two different photographs, either one of which may be brought to view. For stereoscopic purposes the corrugations in the paper should be more pronounced and deep, as indicated by Fig. 4 of the drawings. For this two negatives of the same view, taken from slightly different positions, are used; one negative being then used, as above described, for printing on one side of the corrugations, while the other negative is used for printing upon the opposite sides of the corrugations. The same sheet will disclose two views of the object corresponding to the two impressions upon the retina of the eyes. The sheet with the two photographs thereon, being held at a proper distance from the eyes, so that one

eye sees the photograph only on one side of the corrugations, while the other eye sees the photograph only upon the other side of the corrugations, the usual stereoscopic effect will be produced. The claims are (1) a sheet of cardboard provided with small parallel corrugations, having a sensitised sheet thereon and produced under non-actinic rays, having upon the sides of said corrugations facing in one direction consecutive portions of a photograph produced by a negative in a special position, so that when viewed from said side the consecutive

Fig. 3.

portions combine to disclose a complete photograph, and having upon the opposite sides of said corrugations consecutive portions of another photograph produced by another negative in another position, so that when viewed from said opposite side the consecutive portions of said second photograph combine to disclose a second photograph complete to the observer, substantially as described; (2) the process of printing photographs, which consists in exposing to the light through a negative, corrugated paper consisting of a sensitised paper upon cardboard so that the view will be printed in sections only on the sides of said corrugations facing in one direction, and next exposing the same paper through a second negative, so that the second view will be printed in sections only on the opposite sides of said corrugations, substantially as described; (3) means for the display of duplex photographs so that a picture displayed upon the sides of the corrugations facing in one direc-

Fig. 4.

tion, with a second picture displayed upon the sides of the corrugations facing in the opposite direction, is seen alternately by a light so arranged as to throw its rays on the first picture, and by a second light so arranged as to throw its rays on the second picture, substantially as described. Hiram Codd Deeks, 486, Broadway, Paterson, New Jersey, U.S.A.

#### CATALOGUES AND TRADE NOTICES.

L. GAUMONT AND Co., of 22-27, Cecil Court, W.C., have issued new price-lists of the chronophone, which is a combination of the phonograph and cinematograph, and also of some new and up-to-date cinematograph films.

J. EPSTEIN AND Co., of Rupert Street, Bristol, have opened a new department for 20 by 16 enlargement frames, and can now offer them at greatly reduced prices. They are also offering a special sample case of these frames, which is well worth attention.

THE annual beanfeast of the employees of J. H. Dallmeyer, Limited, was held last Saturday at Brighton, and a most enjoyable day was spent on the beach and in the afternoon in a drive to the Dyke.

## New Apparatus, &c.

The "Skyshade" Shutter. Sold by T. Emil Busch Optical Company, 35, Charles Street, Hatton Garden, E.C.

The design of this shutter is to give a longer exposure to foreground than the sky, which is effected by a leaf or blade which rises slowly from the bottom to the top, and then falls rapidly so that when set to a slow exposure the foreground would receive a full exposure, whilst the sky would probably only receive one-eighth of that. It has a range of speed from 1-100th to 1 second.

and by setting the one indicator at 1 second and the other "time," the blade will rise and remain at the top till the bulb is released again. Having two regulating levers, each with independent mechanism, a great variety of exposures can be given. A very ingenious clamping ring, actuated by two levers, is fitted which enables it to be adapted to any lens.

The shutter is excellently made, and is a useful accessory to the practical worker.

IN our notice of the Zeiss Stereo-Palms in our issue for 13 ult. we stated that the Tessar or "Wray" lens could be easily inserted on its panel; the last lens should have been the "Unar."

## New Materials.

Japine. Made by the Platinotype Company, 22, Bloomsbury Street, Oxford Street, W.C.

This new variety of the platinotype paper, which created considerable attention at the Convention, has been sent us for trial and has given us some excellent results. It is sent out in two varieties—semi-matt and glossy—and the colour of the prints is rich sepia.

As with all other platinotype papers, it must be kept quite dry and it is exposed till all details, except in the highest lights, are visible. A special "Japine" developer is issued, which should be dissolved in hot rain or distilled water, and then about one-third of the bulk of pure glycerine should be added. This developer will keep indefinitely in the dark, and is used at a temperature from 100deg. to 120deg. F., or it may be used cool at 80deg. Certainly the higher temperatures give the richer results, and except for very thin and flat negatives, these will probably be preferred by the majority of users. The duration of development is from two to four minutes, according to the temperature, and the print should then be immersed in the usual three clearing bath of hydrochloric acid, then washed in four or five changes of water for about twenty minutes. The prints must then be immersed in a 5 per cent. solution of glycerine.

We have carefully tested this paper both by printing under negatives in the usual way, and also under H. and V. squares, with densities ranging from bare glass to 3.01—that is, with a range

capacities from 1 to 1,024, which is far wider than is ever met with in practice, and we find that with the glossy paper the full range of gradations is recorded. With the semi-matt paper the shadows are not quite so luminous, and consequently the scale runs a little shorter.

Our attempts to solarise the paper, notwithstanding continuous printing in the sun, have failed. It can be worked exactly like old platinotype papers, and is amenable to brush development precisely the same way. The surface will take water colours excellently.

To sum up, Japine platinotype paper is a new material of distinct character that possesses a scale of gradation and luminosity in the shadows which we have rarely seen equalled. There is nothing to learn for platinotype workers; there is great latitude in printing, and the colour obtained is an exquisite rich sepia. Considerable control over results is also obtainable by variation in the temperature of the developer, and by this means it is suitable for every class of negative.

#### FORTHCOMING EXHIBITIONS.

August 6: Andover and D. H.S.—Sec., W. I. Gradidge, Jubilee House, Andover.

September 14 to October 27: The Photographic Salon.—Sec., Gerald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Cunningham, Tooker Road, Rotherham.

Rotherham Photographic Society.—Annual exhibition. "Open." October 17 to 20. Entries close October 8; exhibits, October 13.

November 16 to 21: Southsea Amateur Photographic Society.—Sec., F. S. Hoyte, "Lismire," Stafford Road, Southsea.

November 20: Sefton Park Photographic Society.—Sec., A. W. Carr, 34, Loudon Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, Sackville Road, Hove.

December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Barber, "Oakdene," Highfield, Southampton.

1907.

February: Birmingham Photographic Society.—Sec., Lewis Lloyd, Trich Union Chambers, Birmingham.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Mason, 35, Molesworth Street, Dublin.

October 24 to November 14.—West of England Exhibition (Photographic) Section. Entries close October 1. Sec., A. D. Breeze, 41, Lion Street, Plymouth.

LUDICROUS incident, in which the dramatis personæ were a giraffe and an amateur photographer, occurred at the Zoo last week, being only relished by the few spectators. The man with the camera was preparing to take a snapshot of the mighty quadruped behind the bars, and with this object had obscured his head beneath the giraffe's cloth. His surprise, however, may be better imagined than described when, just at the crucial moment, the stiff-necked creature, in a supreme effort, reached over the bars and made a grab at the man on his head.

THE annual excursion of the Lancashire and Cheshire Photographic Union will take place on September 8 to Liverpool, whence several parties by boat and rail. The Oldham Photographic Society has rejoined the Union, which now numbers about 3,300 members.

At the Campbell College, Belfast, the first prize scholarship award has been made to J. C. T. Burgess, and the second to C. R. L. Witt, for photography.

## Commercial & Legal Intelligence.

**SELF-DEVELOPING Plate Company, Limited.**—Registered July 20, with capital £25,000 in 15,000 7 per cent. participating preference shares of £1 each, and 40,000 ordinary shares of 5s. each. To acquire any British or other patents relating to apparatus in connection with photography, photographic plates, films, and the development thereof, and chemicals, materials, and accessories. To adopt an agreement with Kelly and Benthall, and to carry on the business of manufacturers and factors of, agents for and dealers in, photographic requisites, etc. Minimum cash subscription, £12,500. The first directors are: B. Humphreys, W. F. C. Kelly, W. Slark, R. H. Martin, and C. W. Ponsonby. Qualification, £200. Remuneration, £100 each per annum and 5 per cent. of the net profits in excess of 20 per cent. dividend. Registered office: 7, Southampton Street, Bloomsbury, W.C.

**DOFF V. SACHS.**—This was an action by Ignath Doff, trading as Doff Brothers, of Manchester, photographer and publisher of picture postcards, to restrain Albert Sachs, photographer, of Bradford, from selling, or offering for sale, in the form of picture postcards, or by way of advertisement, any photographs or pictorial representations of any of the theatrical performers respectively known as Daisy Jerome, Mabel Lait, and Godwynne Earle, produced from negatives taken or made by or for the defendant in the course of or on any occasion of his employment by or contract with the plaintiff for taking photographs of the aforesaid performers. Damages were also asked for. Mr. J. F. Waggett appeared for the plaintiff; Mr. Cozens Hardy appeared for the defendant. Mr. Waggett said the plaintiff was a publisher of picture postcards, carrying on business at Manchester, and the defendant a well-known photographer at Bradford. The cause of complaint was that the plaintiff, having arranged with certain ladies in the theatrical profession to be photographed for him by the defendant for the purpose of having their pictures reproduced upon picture postcards, sent the ladies to the defendant under an arrangement with the defendant for a number of negatives to be taken and supplied to the plaintiff, and that the defendant took advantage of the circumstances to take and retain for his own use various other negatives of the ladies, and so broke the implied contract with the plaintiff. Mr. Justice Warrington: Defendant is not making use of the photos he took for you? Mr. Waggett: No, but of some he took on the same day. The latter photos were all taken in the course of the employment for the plaintiff. Mr. Justice Warrington: The point is that the defendant took the photos on the occasion when the ladies visited him for the benefit of the plaintiff. Mr. Waggett said that was so—these ladies were brought to the defendant's studio as works of art. Evidence was given for the plaintiff to the effect that the ladies' object in sitting was to obtain publicity, and that no permission was given defendant to take photos for himself, except in the case of Miss Earle. No evidence was called for the defence. Mr. Justice Warrington said he failed to find an implied contract that Sachs would take only negatives for the plaintiff at the appointment made in consequence of the arrangement of the plaintiff. It was admitted the ladies were free agents, and if they had gone to the

defendants an hour later and asked him to photograph them the plaintiff could not have complained. The result was that there must be judgment for the defendant, with costs.

**BUSINESS WORRIES.**—At the West London Police Court on Saturday, Sidney Wyatt Whiteman (26), a photographer, living at Northcote Road, Clapham Junction, was charged with attempting to commit suicide by cutting his throat. Mr. Oswald Hanson appeared for the accused. Police Constable 583 T stated that he was called to the defendant's business premises at New King's Road, Fulham, and found him sitting in his studio with two slight cuts on the throat. Mr. Hanson told the magistrate that the accused had had business worries. He gave his promise now not to repeat such conduct, and on that promise the magistrate discharged him.

**ARTHUR HENRY SEELEY DRAYCOTT** and John Arthur Draycott (trading at the Draycott Galleries), photographers and dealers in works of art, carrying on business at 138, The Parade, Leamington, and at 64 and 65, New Street, Birmingham.—The above-named debtors appeared for their public examination at the Birmingham County Court on Thursday, before Mr. Registrar Lowe. The statement of affairs filed by the debtors disclosed liabilities amounting to £894 and a deficiency of £829. Mr. Rahnnett appeared for the petitioning creditor, and Mr. O'Connor for the bankrupts. In reply to questions put by the Official Receiver, the bankrupt, John Arthur, stated that he commenced business in 1881 as a photographer at Sutton Coldfield. He was without capital, and after trading for three years he executed a deed of assignment, a dividend of 6d. in the pound being paid. In February, 1901, he had businesses at Walsall, Birmingham, Northampton, and Leamington, which he transferred to a company formed in that year with a capital of £20,000. The company undertook to pay the trade liabilities, and the bankrupt received 8,993 shares. Shortly afterwards the bankrupt interested himself in the cycle trade, and, having invested £750 in a cycle company, became a director. He subsequently increased his holding. Through the failure of the company he stated that he lost £1,675, and he had to borrow money to discharge some guarantees that he had given on behalf of the company. All those have not been discharged. The bankrupt remained with Draycott, Limited, as managing director, in which capacity he received £500 a year until 1902. In July, 1905, he made arrangements with his son, who was a photographer's assistant, for the purchase of a business at the Parade, Leamington. A friend provided him with the capital. They commenced trading under the style of the Draycott Galleries, the business being managed by himself, as the other bankrupt was engaged in a situation until November, 1905. Afterwards the latter went to Leamington to assist in the business. A branch shop was also opened at Birmingham. The businesses were not successful, and creditors began to press, with the result that payment was suspended. Arthur Henry Seeley Draycott having given evidence, the hearing was adjourned.

## Dews and Notes.

The following were the awards in the recent prize competition held by the Birmingham Photographic Company, of Criterion Works, Stechford:—1st prize, £2 2s., F. W. Beken, Blenheim House, Cowes, I.O.W.; 2nd prize, £1 1s., A. Avery, 319, Queen's Park Road, Brighton; 3rd prize, 10s. 6d., E. J. Picken, Bucknall. Another competition, which expires on September 30 next, has also been arranged. We are requested to point out that the firm had a considerable number of applications for papers direct from amateurs, who stated that they could not obtain the same in their district. Full details of the competition will be sent to any dealer on application.

At the rooms of the Liverpool Amateur Photographic Association an exhibition of pictorial photographs by Mr. Joseph Appleby is now open, and will close on August 6.

Mr. W. P. WATMOUGH will, at the end of the month, act as demonstrator for Thos. Illingworth and Co., 6, Willemsen Junction, N.W.

At a meeting of the Physical Society, Mr. J. S. Dow, in a paper on "Colour Phenomena in Photometry," said that the question often been discussed whether it was possible to compare light of different colours, but he had found that it was chiefly a matter of practice. He submitted curves showing the effect of altering the distance of the eye when an incandescent mantle is compared against a gas standard, with the Joly photometer. Difference of 5 per cent could easily be obtained. The Purkinje phenomenon usually regarded as producing uncertainty in ordinary work, was only noticeable with very small illuminations and with comparatively large fields of view. He had also conducted experiments which showed that Flicker photometers seemed to be affected by colour phenomena, but to a small extent than ordinary ones. In any case, whether a Flicker or ordinary photometer was adopted, it was necessary to specify the size of the field, the distance of the eye, and the order of illumination used, in order to get consistent results.

ACCORDING to the "Times Engineering Supplement," the French Minister of Public Instruction, M. Briand, has arranged that professors and teachers throughout France are in future to employ the following distinctive abbreviations for the various weights and measures:—For measures of length.—Myriamètre, Mm; kilomètre, Km; hectomètre, Hm; décimètre, dam; mètre, m; décimètre, centimètre, cm; and millimètre, mm. The use of capital letters for the three largest denominations is intended to prevent confusion. For areas.—Hectare, ha; are, a; and centiare, ca or m<sup>2</sup>. For measures of bulk (timber) décastère, das; stère, s or m<sup>3</sup>; and décistère, ds. For measures of mass and weight.—tonne, t; quintal métrique, q; kilogramme, kg; hectogramme, hg; décagramme, dg; gramme, g; décigramme, dg; centigramme, cg; and milligram, mg. For measures of capacity.—Kilolitre, kl; hectolitre, hl; décalitre, dal; litre, l; décilitre, dl; centilitre, cl; and mil or millilitre, ml.

At a recent meeting of the Société de Pharmacie de Paris Al has stated that the addition of 1 per cent. of sodium and calcium chloride to solution of hydrogen peroxide acts as a more effective preservative than the substances generally used, such as phosphoric acid or alcohol.

THE Health Resorts Development Association have sent us copies of their booklets dealing with Southend, Harwich, Malvern, Bournemouth, and Kingston-on-Thames. These contain some useful information, and can be obtained, post free, by sending a postcard to town clerks of the various places.

FIRST place in the pictorial section and first also in technical of the Torbay Camera Society is secured by M. Marillier's print "Japanese Peonies," in the June Album. It is a piece of work of considerable excellence. The subject is beautiful in itself, the blossoms lending themselves to photographic treatment well. The grouping is well arranged. The printing method adopted is carbon, and the technical quality of it is high class. Another contribution—"White Lilac"—falls considerably below awarded print in quality. Mr. A. J. Anderson's "Design for Frieze" is also a flower subject, most admirably handled, and very enjoyable. Mrs. Marillier contributes "Fine Study of Tulips," a portrait of a praiseworthy character. Mr. C. F. Rea presents two prints, old-fashioned houses in the country, which would be acceptable in any exhibition, evincing much skill and showing good taste in selection. Miss Bullock's architectural work—of which better example is "South Aisle, Exeter Cathedral"—shows much promise, and indicates considerable technical skill. Mr. A. Cox's "Bridge at Richmond" is soft and "sketchy," but it is photographic, and looks like nothing else. Mr. G. Drury has a rendering of velvet texture in a figure study, and the technical quality of the print is good generally. Mr. E. W. Garland is very successful in some country-life scenes. Mr. J. W. Smith has a charming seaside subject, a group of children, "On the Sand." delicate and full of good quality. Colonel W. Fothergill Mullen contributes a figure study, and an example of flower photography. The Album is of such good average that it is quite a travelling exhibition, and ought to do much as a valuable incentive to the members of the Society.

MR. JAS. H. HARE, whose excellent work for "Collier's Weekly" in the Russo-Japanese War we have already had occasion to mention, had another exciting experience early last month. He sailed in a balloon from New York, and travelled the entire length

of Manhattan Island, and then the balloon sank into the sea. Mr. Hare, who had been busy all the trip photographing, was completely immersed, and although he lost his camera he was able to save the plates, of which he writes to say, that notwithstanding their immersion in salt water, eight developed all right, except for an inch round the edge, where they were too thoroughly saturated with salt water.

MISS MARIE CORELLI's new novel, "The Treasure of Heaven," contains as a frontispiece her portrait, which is given, according to the authoress, "owing to the fact that various gross and, I think may say libellous, fictitious misrepresentations of me have been freely and unwarrantably circulated throughout Great Britain, the Colonies, and America, by certain 'lower' sections of the pictorial press, which, with a zeal worthy of a better and kinder cause, have been driven by this means to alienate my readers from me." The portrait is put forward as a genuine and unvarnished presentation of the authoress, taken by a photographer who, "at the time of my submitting myself to his camera, was not aware of my identity." Miss Corelli used the name of a lady friend, who arranged that the proofs of the portrait should be sent to her at various different addresses, and it was not until "The Treasure of Heaven" was on the point of publication that she explained the real position to the photographer. "That I thus elected to be photographed as an unknown, rather than a known, person was in order that no extra pains should be taken on my behalf, but that I should be treated just as an ordinary stranger would be treated, with no less, but at the same time certainly with no more, care." All of which is extremely pretty reading, but the cynic may question as to whether, after all, anyone really cares how the authoress looks, and whether there are not more ways than one of getting "bold advertisement."

DURING the laying of the foundation-stone of a new Roman Catholic church at Clapham Common on Saturday, the Bishop of Southwark, attired in his vestments, noticed a camera pointing towards him. He wheeled sharply round, and, raising both hands, exclaimed to the photographer, "Stop that at once." The photographer moved into the crowd, but kept the lens still pointing towards the bishop, who, however, refused to resume the ceremony until the camera was taken entirely out of range.

## Correspondence.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A NOTE ON THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—Mr. Ferguson's letter appears to me to explain Mr. Payne's difficulty more clearly than I could have done. Of course, Mr. Payne's numbers for K were not wrong at all; they were quite right, but K does not measure the rate of development—it only compares the rate of development for two plates which have the same  $\gamma^\infty$ , which Mr. Payne's plates, as was shown by Mr. Sheppard, had not. But if you know K and  $\gamma^\infty$ , then you know all about the development curve of a plate. There is nothing wrong with our tables—they are simple mathematical tables, the one giving the relation between  $\frac{\gamma}{\omega}$  and  $\log e \frac{\omega}{\gamma - \omega}$ , and the other between  $\omega$  and  $(1 - e^{-\omega})$ , and the fact that the values calculated

by Mr. Sheppard agreed with the numbers found by Mr. Payne shows in the most convincing way that there is nothing wrong with the theory giving the shape of the development curve either.

With regard to Mr. Gascoigne's question, the acetylene light we use has been reduced to the standard candle, and consequently Hunter Driffield's number of 34 can still be used. Some of the new colour sensitive plates form excellent examples of the necessity of screening the light, as if they be tested by candle or unscreened

acetylene light they will give absolutely ridiculous numbers when compared with an ordinary plate.—Yours, etc.,

C. E. KENNETH MEES.

To the Editors.

Gentlemen,—I must thank Mr. Ferguson for his extremely interesting and lucid explanation of July 27, which removes the false impression I had, that the constant k was intended to be of practical use. I see now that it is only a link in a chain of mathematical formulæ, which are useful when all the available information to hand is a knowledge of the values of k and  $\gamma^\infty$ , but hardly likely to supersede, in practical plate testing, the valuable method introduced by Mr. Driffield.

To quote the actual times of development is a less pedantic, but much more serviceable, method than quoting the constants k and  $\gamma^\infty$  and asking each plate user to work out his own salvation mathematically.—Yours truly,

ARTHUR PAYNE.

### ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION.

To the Editors.

Gentlemen,—May I call the attention of your readers to the forthcoming exhibition of the Royal Cornwall Polytechnic Society, which will be held in Falmouth during the first week in September? This exhibition is one of the most important events in the West of England, and it invariably attracts a very large number of good and interesting examples of the various branches of art and science which it embraces.

The schedule for the photographic section has been entirely revised and re-arranged in accordance with the practice of the leading photographic societies. It is desired to make this section as thoroughly representative as possible of the best photographic work of the present time, and the co-operation of all good photographers is earnestly solicited.

There are three divisions: (A) Pictorial Photography, five classes; (B) Technical Photography, two classes; (C) Apparatus and Trade exhibits. The Society's medals will be awarded at the discretion of the judges—Messrs. Dalzell, T. Savary, M.A., James Clark, D.Sc., W. Naylor Carne, Robert Fox, and Henry W. Bennett, F.R.P.S.

I shall be pleased to send entry forms and full particulars to any of your readers.—I am, sir, yours truly,

HENRY W. BENNETT.

17, Ranelagh Gardens, Ilford.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I have read the letter of "A Disgusted Assistant" with interest, and there is much to be said from his point of view. Probably no profession has been so thoroughly permeated by the worst form of amateurism as that of the photographer, and the fact that the trouble is not confined to one section largely accounts for a deal of mischief, misunderstanding, intolerance, and so forth, one with the other. If the employer be ignorant, as he often is, it is quite natural to find the employee equally so.

Recently I developed my business to the extent of taking over a fair amount of trade work—i.e., developing, printing, enlarging, etc., for amateurs. I was not brought up to the profession of photography, but as I have studied and practised it for thirty years, and passed all the examinations possible connected with the art, as, in addition, I have as many medals and so on as I want, and have been mixed up with professionals all my life, I claim to know as much of photography as most.

I engaged five assistants for the work—four young women and a young man for outdoor work when necessary, retouching, and so on. All five had received some training (so-called) at professional photographers, but however hard a fact that may be, it is difficult to realise. Twelve prints from one negative, and all differently printed, is common, the waste in paper which occurs I am certain no professional would or could stand. Similarly with developers

and solutions generally. My enlarger will, for instance, prepare her dishes, etc., every morning, and I have known her, more than once, to pour into one of them two quarts of metal developer, costing about 1s. 6d., which was not used after all, as the bromides done were developed with metal hydroquinone, a much cheaper solution. The more expensive metal was, however, tossed out with the least unconcern, as one might say, "Hang the expense!" Another will mix up a gallon of toning bath (15 gra. gold chloride), use it for a batch of prints, which may equal four sheets of paper or six; down the sink it goes as soon as done with. Dirty dishes left about, all the corks left out of bottles, dirty benches, splashes of hypo, spillings of alum and salt, and all the careless incidentals that lead up to stained and spotty prints and negatives, together make up a state of things to which I, for one, am not accustomed, and I am asked to believe that these young people are professionally trained! What sort of training is this? I know many professional photographers of high class and the other, but I do not know one where there is an unstinted—practically unlimited—amount of material allowed. Of course, all this is gradually being rectified, certain drastic remedies being applied; but it means incessant watching and scolding and fault finding, which becomes a hateful state of things. Only two out of the five can be trusted to trim prints for them to be squarely and fairly balanced, and as to platinotype printing, cloud printing, vignetting, and carbon work, well, these I have to do myself, or, rather, teach them; provide cut and trimmed papers, and they are put into the frames so carelessly that there is no saving of time. My place is well fitted with dark rooms and work rooms, plenty of sinks, dishes, measures, dusters, and towels, electric light, and a good water supply. Of course, not a soul of the five would switch off the light when not wanted, nor turn a tap to lessen the waste of water!

These young people—not so very young, either—have all served time more or less with professional photographers. I got testimonials and references in the usual way. What sort of men these may be I cannot imagine, but the inference may safely be that it is a case of "Like man, like master," and I wonder more professionals are not on their beam ends, if these young people are samples of the persons who initiated (?) them into the mysteries of the art.

The professional amateur we know. My experience of him has been that he has a fair conceit, and does not under-value his work; to that extent he is to be commended. At any rate, he does far better work than the assistant professional, who is the merest and most ignorant dabbler—possible immature would be a better word to apply than amateur—if I may be allowed this slight divergence from the orthodox.

But where these young people get their careless habits and ways I cannot imagine. The present times are supposed to be "hard," and many experience undoubted difficulties, not only in finding what one terms a "billet," but even any kind of profession. In my work rooms there is material to turn out assistants conversant with all the usual branches of photographic work; enough work to make them expert operators, and with it all—no cheeseparings. But what does one find? Not the slightest sense of any ambition to make themselves really useful and reliable members of the photographic profession, at which—in spite of all the talk—there is still a good living to be made.—I am, dears Sirs,

A DISGUSTED EMPLOYER.

To the Editors.

Gentlemen,—It is gratifying to know that there are a number of assistants who take pride in their professional career as photographers and do their level best to uphold their dignity by their efforts in keeping the meddlers out of the field. I endorse the statements made by "Disgusted Assistant," for things have come to such a pitch that assistants must combine and have things as they want them, not in such a state as they are at present. It is not at all surprising that such a number of assistants are disgusted at the state of affairs now existing, when, in the first place, in some cases they pay heavy premiums, work and study hard, and put up with no end of humbug and disrespect at the hands of others, then finally they become proficient photographers, but only to get knocked out by the so-called

good amateur that is not objected to; but not in high class houses does this follow, although at times the inexperienced duffer will, by some means or other, work his way in, especially in cases where he has a friend an operator, whose word carries a certain amount of weight. What we assistants should do is to combine and work in harmony with one another and make up our minds not to work for the interests of these "amateur professionals," or any unscrupulous professional photographers, thus by so doing their work will not come up to the standard, and will not be approved of by the public in a great many cases; so eventually they close their "hut studios" to follow their original occupation. We could also settle the wages question that is troubling so many of us by arranging a scale or rate according to grade of certificate we qualify for. The working hours for assistants could greatly be improved, which would also be to the interest of employers. Assistants are strong as a body, and could do great credit to the profession to which they belong. It does very little good writing and jangling with each other. We must do our duty to our employer and the best we can for ourselves, then the business we represent is bound to be a success. If employers fail to do their duty to us, the remedy we have is to seek another situation.—I am, yours faithfully,

C. H. B.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- James Henry Jamieson, 91B, Fishergate, Preston, Lancs. *Photograph of Women Leaving Messrs. Dick Kerr & Co.'s Works, Preston.*
- Ernest Hamilton-Toovey, 36, Royal Parade, Jersey. *Eighteen Photographs of Monk and Novice taken at Mount Orgueil Castle, Jersey, in Different Scenes and Positions.*
- Edwin Frank Fox, 8, Micklegate, York. *Two Photographs of Interior of Wesley Chapel, York. 1. Showing Part of Gallery. 2. With Bible in Foreground.*
- John Henry Barnes, 172, Arkwright Street, Nottingham. *Photograph of Group, containing the Nottingham Cricket Eleven.*
- Joseph Winton Mason, 21, St. Peter's Street, Ipswich. *Photograph of Group containing D. Ford Goddard, M.P., Felix Cobbold, M.P., Mr. Soames, M.P., Spencer Leigh Hughes, Mrs. Goddard, and Mrs. Soames, taken at Oak Hill.*
- Ralph Edwin Collier, 49, Hartington Road, Brighton. *Photograph of Group of the Band of the 20th Hussars.*
- Isaac Perloff, 186, Commercial Road, London, E. *Photograph of Mr. Charlton Keith, Famous Pianist, taken in July, 1906.*

**RIGHT TO NEGATIVE.**—A lady customer asks me how she can prevent a photographer in this town using a negative of herself and family, taken several years ago, which he bought from another photographer when the latter left the town. Copies are being printed, and a use made of them which is causing great annoyance to the lady in question.—E. H. DEBENHAM.

This subject is clearly dealt with in the "Almanac" for 1906, p. 672. Assuming that the lady paid for the photographs, the copyright belongs to her. She can, if she likes, and can obtain the necessary details copyright it even now, and then proceed against the photographer for infringement. On the

other hand, she has a direct remedy, without any reference to copyright, in an action at common law for breach of contract, for there was an implied contract between her and the photographer that the negative shall be used for supplying the customer alone with prints. The case bearing on this is *Pollard v. the Photographic Company*, 1889, B.J., March 29, 1889, p. 215, and in this the judge said, "In my opinion the photographer who uses a negative to produce other copies for his own use without authority is abusing the power confidentially placed in his hand merely for supplying the customer; and, further, I hold that the bargain between the photographer and the customer includes, by implication, an agreement that the prints taken from the negative are to be appropriated to the use of the customer only." A perpetual injunction was granted against the photographers, who also had to pay the costs of the action. That the photographer has bought the negatives does not, in our opinion, release him from the implied contract between the vendor of the negative and his customer, for if the benefit of possession of the negative are the purchaser's, so also must be disadvantages.

**UNDER.**—The flash is certainly a little unusual, and it might be worth while sending to the Royal Meteorological Society, 70, Victoria Street, S.W. We rather think that some of the curious effect is due to the fact that the flash was either to or from you, and not straight down as the others.

**BROM.**—1. There is no special method. 2. No special books published. We hope to deal with the subject shortly.

**OUR PHOTOGRAPHY.**—Do you consider that it would be advisable for me to interest myself (in a practical way) for commercial purposes in "colour photography"? If so, which method do you think best to start with?—F. A. SWAINE.

Most decidedly. As to the best process to adopt, this must necessarily depend upon what the results are required for. We should say that a method of making transparencies by one of the superimposed stained film processes should be learnt, and also one or two of the printing methods. We cannot say which is the best, but so far we think the carbon process holds the palm. There are others which are cheaper, however.

**M.**—When appealing to us we shall be glad if you will indicate (if possible) the method of working. The stains are due to sulphuration caused by the improper use of a combined toning and fixing bath or improper fixation and washing. In the case of the terrace, we should certainly say that this card laid underneath others in the fixing bath, and so was improperly fixed, as the outline of the stain is distinct.

**RIGHT.**—I have just been asked to copy a photo from a South African studio. It is printed "Copyright; not to be reproduced," on the back. May I reproduce this for my client? The reason I ask is, not that I would for a moment infringe the Copyright Act, but that I am sure the people in the group paid for the copies, and therefore they can do as they like with them.—**ANXIOUS.**

If the print is copyrighted you have no right to reproduce it in any shape or form without the permission of the photographer, to whom the copyright belongs.

**M. SMITH.**—We are sorry, but have no means of obtaining the information you require. There are two Australian photographic journals which might possibly be of service to you.

**REDUCING NEGATIVES.**—I would be glad to know of a safe reducer for negatives which have been over-intensified by the mercury and ammonia method.—**SHIRE**

One of the simplest methods is to immerse the plate in a  $\frac{1}{2}$  to 2 per cent. solution of hypos in a 10 per cent. solution of sodium sulphite, or in a solution of potassium cyanide,  $\frac{1}{2}$  grains to 1 ounce of water. They all act slowly and evenly, but we prefer the last.

**HYETT.**—It is absolutely impossible to tell the value of a lens from prints. Besides that, you give no information as to the aperture you used, so that we cannot judge of the covering power of the lens.

**VARIOUS DYES.**—I have lately been experimenting with various dyes to obtain certain effects upon gelatine papers. I have obtained successfully an orange red colour by using a mixture of eosin and methyl orange. But I am uncertain of the keeping qualities of these dyes. Methyl orange turns to a vivid purple with the least trace of an acid, and eosin is, I believe, a fugitive colour. I have also tried a Judson's dye scarlet, but this seems to be composed of eosin, while a yellow "Dolly" dye has exactly the effect of methyl orange when treated with an acid. Can you tell me if I can obtain any dye such as I want—that is, either yellow, red, or orange, that are not affected by light or atmosphere, or can I make a suitable stain?—S. E.

Our correspondent does not give us just one important particular—that is, whether the dyes are used in aqueous solution or not; but we presume they are, then all the eosine dyes are extremely fugitive. With regard to a red dye, cochineal red A, made by the Badische Anilin und Soda Fabrik, is a fairly stable dye, but better than all is a solution of carmine in ammonia. If some carmine-nacaral or other good carmine is obtained and rubbed into a cream with water, and then sufficient liq. ammonia fort. added to make a perfectly clear solution, a fairly stable colour is obtained. For a yellow dye metanil yellow S is also excellent, or walk-yellow; the former is made by Oehler and the latter by Cassella and Co. Methyl orange is only stable to light under certain conditions, its sensitiveness to acids being against it. Being quite in the dark as to the exact purposes for which the dye is required, we cannot give much satisfactory information, but we may point out that the light stability of many dyes is enormously increased by treating them with a weak solution of copper sulphate, which presumably would not hurt the print.

**OWNERSHIP OF NEGATIVE.**—I was asked to copy a picture 12 x 10 and supply two copies from same. These were done satisfactorily, and now my client demands the negative without payment for same. No mention was made about requiring the plate at the time of order. I should be glad to know if I am right in retaining same unless paid the price charged—i.e., 10s. 6d.—H. I. J.

This question is very clearly answered in the Editorial article in the *ALMANAC* for 1906, from which the following is an extract:

"Although the photographer, both under copyright and common law, has no right to use the negative save by the customer's request, yet the customer cannot claim it as his property. This position has been upheld in the county courts over and over again. '*Dixon v. Ward*,'<sup>1</sup> '*Andrews v. Capper*,'<sup>2</sup> '*Theobald v. Thomas*,'<sup>3</sup> and '*Harbord v. Brewer and Company*.'<sup>4</sup> But curiously, no case specially raising the question of custody of the negative came before the High Courts until 1903, when a decision of considerable importance was given. The case was '*Rotary Photographic Company v. Taber Bas Relief Company*.'\* The Rotary Company, in order to facilitate the execution of an order for a considerable number of prints for the Taber Company, had to make reproductions of the original negatives, and these negatives were separately charged for. Nevertheless, the Court held that the negatives so made were the property of the Rotary Company. This decision sets at rest any question which may arise as to the ownership of the negative taken by a photographer in the ordinary course of his business. The case is practically the same as when an order is given to a letterpress printer. The object of the order, as usually given, in both cases, is to obtain so many impressions. In the one case, the photographer, in order to produce these impressions, has to make a negative; in the other, the printer has to make a forme of type. The delivery of the impressions made, in each case, constitutes the fulfilment of the order, and the possession of the negative or the forme remains with him who made it. There is a noticeable point about this case of the Rotary Company v. The Taber Company, which, as I have said, is the only High Court decision on the subject of the ownership of the negative, and it is this:—The complete report of the case discloses that

1884, p. 372. (2) 1884, p. 202.  
(3) 1895, p. 114. (4) 1899, p. 792.

\* '*The British Journal of Photography*, March 27, 1903, p. 250.

the production of the negatives in dispute was necessary for the fulfilment of the order. The order was for prints, and the negatives were made of necessity, in the course of producing the prints. It was not an order for negatives and an order for prints from them. The point is a fine one, but no point is too fine for legal disputation, and it should be borne in mind by photographers in making quotations for commercial work (such as machinery and articles for the illustration of price-lists, etc.), that a quotation for the prices of making negatives and for prints is often asked for. A quotation or an invoice for, say, 10s. each for negatives and 1s. 6d. each for prints, might clearly be open to a very different construction legally, from a quotation for 11s. 6d. for taking the photograph and supplying one proof, subsequent prints 1s. 6d. each." It is obvious that you have a perfect right to detain the negative until paid for.

S. TIMOTHY.—The negatives were returned to our correspondent, but we shall be pleased to examine any of yours if you send them up.

ALOHA.—There is no work specially devoted to astrophotography. You will find it treated of in the larger works on astronomy by Chambers and Miss Clerke.

BLUE-BLACK ON BROMIDE PAPER.—Can you give me a good formula for bromide paper to produce a good blue-black tone, using amidol? I might mention I have tried several formulae, but fail to get the right tone; I either get a greeny-black or a flat grey. What I want to get is a rich blue-black.—A. FOSTER.

We have always been successful with:

Amidol .....	50 grains.
Sodium sulphite .....	500 grains.
Potassium bromide .....	2 grains.
Water .....	20 ounces.

When freshly-made. Greeny-blacks are due to under-exposure, and greys to over-exposure. If the exposure is correct, a good blue-black is obtained with this.

LENS QUERY.—I have bought a portrait lens; the glasses are 3½ in. in diameter, but there are no central stops with it. The only one there is fits into the hood of the lens, which bears no name. Will you please tell me if it will take whole-plate negatives?—C. WALTERS.

It is impossible for us to say what the lens will do without examining it. As there is no name on it, and it is not fitted with central stops, but with a front one, we should say it is a very old one, of French make.

FACTORIES ACT (F. and Co.).—As your place comes within the Factories Act you must conform with it. You cannot work the young people longer than from eight to eight, with one hour and a half off for meals. They must have one half-holiday each week, and all Bank Holidays, as well as Good Friday and Christmas Day, without any deduction from their wages. Also, they must not be employed on Sunday. From this you will see you have been infringing the law, and have rendered yourselves liable to penalties.

PRINT QUERY.—Will you kindly tell me by what process the enclosed print was produced? I am told it is carbon, but I do not believe it as it is free from gloss anywhere.—T. WATSON.

The print is undoubtedly a carbon one, made by the single transfer process on a fairly rough paper. The print has been returned as requested.

REPAIRS.—A few months ago I bought a business and the lease, with four years to run, was transferred to me, by the landlord, from the previous tenant. Within a week I found that the roof of the studio leaked like a riddle. I at once complained to the landlord, and he told me that he would not do any repairs, and that if I wanted any done I must do them myself. Is he not bound to do them, seeing that the roof was in such bad condition when I took the premises?—WORRIED.

No. You will have to do the repairs. You did not take the premises direct from the landlord, but from your predecessor, and the lease was transferred to you, and you took over the

responsibilities with it. If you read through its covenant will, doubtless, see that the tenant has to keep the place in thorough repair.

ELECTRIC LIGHT.—I am thinking of adopting the electric light studio for portraiture, but principally for copying purposes. Will you please tell me which would be the best to the enclosed arc or the Cooper-Hewitt light, and which would be the cheapest to instal? I may tell you that the current should have would be the direct one, at two hundred volts. INQUIRER.

Opinions are at present somewhat divided as to which is better. The enclosed arc has come very much in favour of late, and it does not cost so much as the other for its installation, that is if you have five of the Cooper-Hewitt tubes, a number usually recommended for portraiture.

PLATINOTYPE FRAUDS.—Hitherto I have always supplied good platino-types when they have been paid for. But other photographers in the place have for a long time past been supplying bromides for them. I now think of doing the same as the platinum paper is so dear. Is there anything illegal in doing this if I use platino matt paper for the purpose?—YORKS.

Yes, there is; and you will render yourself liable to proceedings under the Trade Marks Act, the same as your neighbours have already done. Anyone who has been defrauded by the supply of bromides when they have paid for platino-types can take proceedings.

"TITLING CARDS."—Kindly inform me of the best (or value) method of putting the title on P.O.P. postcards; not a quantity required from each negative, it is not worth sending to a printer. Also (2) How can I recover gold which I have posited all over inside of the jar that toning bath has kept in for months?—HENRY LONG.

1. The simplest method is to obtain a fount of moving rubber type, with which any title can be set up and printed direct on to the card. By the same method, only using rubber type, the title can be put on the negatives direct to print. 2. Mix 1oz. of nitric acid with 3oz. of hydrochloric acid, both full strength, and then run round the jar; this dissolves all the gold, and by evaporating the solution thus obtained impure chloride of gold would be formed, or by adding sulphate of iron and boiling the gold would be precipitated.

PLATINUM COMBINED BATH.—Is it possible to tone P.O.P. to a brown using a combined bath containing platinum?—PRINTER.

The only formula we know containing platinum is the following:—Hypo, 2oz.; lead nitrate, 120 grains; alum, 40 grains; sodium formate, 40 grains; formic acid, 30 minims; hot water, 20oz. Dissolve the lead and formate in hot water, and the hypo and formic acid, allow to stand twenty-four hours in a dish, and then add platinum perchloride, 4 grains. Immerse the prints before toning in salt and water. We have very grave doubts as to the permanency of prints treated this way, and, considering how easy it is to obtain black and white bromide and gaslight paper, it is hardly worth while to go roundabout way to get them.

\* \* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

A German writer, Dr. Sedlacek, has written a book in which he discusses from the scientific standpoint the methods of toning bromides. The first part of an abstract of his conclusions and a number of formulæ based on them are given on page 624.

Some notes on the important question of the photographer's window display appear on page 623, and will be followed by later chapters dealing with further aspects of the matter.

The relations between employers and assistants is the subject of further discussion in our correspondence columns. (P. 637.)

Self-developing plates, flashlight apparatus, and a folding camera are among the patents of the week. (P. 632.)

Baron von Hübl continues his observations on the theory of three-colour printing. (P. 627.)

M. Ed. Belin communicates to the French Photographic Society the description of an apparatus for colour sensitometry with which the results are obtained directly on the exposure of the plate. (P. 629.)

An American writer explains his purpose in using a "concentrated" lighting, and the practical measures employed by him in such studies. (P. 626.)

It is announced that by a departure in elementary instruction in Germany photography is to be one of the science subjects taught in schools which stand between the primary school and the technical institutes, such as that at Charlottenburg. (P. 622.)

Recent experiments on fused magnesia suggest that the commercial pure magnesia may be used as a substitute for lime in the oxy-hydrogen lantern. (P. 622.)

A correspondent details his method of packing negatives for posting at the expenditure of little time and materials. (P. 637.)

## EX CATHEDRA.

### The Effect of Air Waves.

An extremely interesting article upon atmospheric effects in astronomical observations appears in the current issue of the "Monthly Weather Review," published by the Weather Bureau of the U.S.A. Special attention has been drawn to this subject by Professor Lowell, of Flagstaff Observatory, to whom we are indebted for the photographs of the Martian Canals. He has pointed out that such delicate markings as the Martian Canals, or even a spectrum line may be distinctly blurred and ill-defined when photographed, although at the first instance of vision the same may be recognised as clear and sharp. This phenomenon Lowell has proved to be due to diffraction effects caused by varying strata of air or rather movements in the atmosphere. In a perfectly still night there may be just beyond perception a boundary to the cool stratum of air surrounding the observatory and telescope, and on this boundary a warmer layer of air rolls and surges along, producing those diffraction effects which are so troublesome. In visual examination the oscillatory swing is recognised as such and mental correction is applied; but if a photographic plate be substituted for the eye, the varying positions of the oscillatory image, being superposed on each other, are all permanently recorded on the plate, so that a large blurred image and not a point is the result. Hence the centre of star images is always taken as the measuring point. Precisely the same argument applies to photography; the spectrum and lines may be photographically recorded as broadened, whilst they are actually sharp. Lowell's remedy for this state of affairs is stopping down, and the improvement has been proved both optically and photographically.

\* \* \*

### Photographing Air Waves.

The above note naturally leads one on to think of the actual photographing of air waves. This has, of course, been done, not only by Professor Vernon Boys in his photographs of flying bullets, but also by Professor Mach of Prague, in similar work. We are not aware, however, that anyone has yet recorded the air waves from a heated surface, and considering the present height of the thermometer there ought to be no difficulty in doing this. One has merely to lie down, with the face close to the surface, of a newly cropped hay or corn field, or even look along a sunlit wall and the air waves, or rather their effects, can be most distinctly seen in the fuzzy appearance of the objects in the distance. This idea was used of old to obtain softness in portraiture, and a lamp burning below the lens and sending a stream of heated air across the field of view was a favourite, and we believe a patented, device for obtaining softness. We are not suggesting a revival of this method, but it might

be interesting to repeat the experiment in order to determine the maximum aperture at which this disturbing phenomenon appears.

### Some Parallels.

Every microscopic and photomicrographic worker will at once recall that well-known phenomenon of "drowning" which the beginner is too apt to ignore. The beginner in micro work, whether visual or photographic, hastily concludes that the more light the more he must see. The result is that too often he drowns the finer detail by flooding his object with light to the total obliteration of the finer detail. The same applies, though to a less extent, in photography. Given a lens of big aperture, the beginner naturally assumes that because he has this wide aperture he must always use it, quite regardless of the such minor things as drowning or obliteration of structure, which is sometimes the most important point.

### Cloud Forms.

The paper read before the Convention, and the letter by Mr. Howden Wilkie in our issue of the 27th ult., will have given quite sufficient data for anyone anxious to take up this fascinating branch of photography. In this month's issue of "Knowledge" there appears, however, a paper by Dr. W. J. S. Lockyer on the subject, which is illustrated by some excellent prints. He elects to use a ten-times yellow screen, a lens aperture of  $f/8$ , and Wellington and Ward's ortho process plates, followed by hydroquinone and caustic soda developers. Mr. Clayden's book on "Cloud Forms" is illustrated by a fine series of reproductions, but in these, as in those in Dr. Lockyer's article, there is one grave fault from the point of view of truth, a point which must not be lost sight of by those who elect to follow either indicated methods of working, if the negatives are required for pictorial purposes. This fault is over-correction. The majority of the illustrations in "Knowledge" give us the impression of moonlit clouds on the deep blue sky which is so often seen at night. The intensity of the blue of a night sky is very marked, whereas that of brilliant sunlit sky is nearly as luminous as the white clouds, and, as a rule, far more so than any portion of the cloud which is in comparatively deep shadow. This over-correction with prolonged development, particularly with a developer prone to give density readily, such as hydroquinone, means that the finer and more delicate gradations in the most brilliantly white portions of a cloud are lost. From a pictorial point of view this is, of course, hopelessly wrong, and except under special conditions it is, we think, equally erroneous for the purely scientific study of clouds.

### Miss Marie Corelli's Portrait.

For some unaccountable reason, the doings of Miss Marie Corelli create more interest than the proceedings of more important personages. Miss Corelli has been photographed, and has thought fit to communicate to the world the particulars of this important event. From her statement it appears that she went to the photographer as an ordinary customer, paying at the time or afterwards for the sitting. These being the conditions, according to copyright law the copyright in the photograph does not belong to the photographer, and the only way he could acquire it was by an assignment in writing. Of course, we cannot say that this assignment has not been made, but it seems very unlikely under the circumstances. The portrait, which forms the frontispiece to Miss Corelli's new book, bears a facsimile of her signature, and the words "From a photograph taken in 1905 by G. Gabell," also the words "G. Gabell, copyright." It is not of any

importance to the world whether Mr. Gabell is or is not entitled to this superscription, but in the event of some infringing the copyright, and should a mistake have been made, some very interesting complications are likely to arise, especially if the photograph has been registered with Mr. Gabell as the proprietor of the copyright and it should turn out that Miss Corelli or someone else is the proprietor.

### Fused Magnesia.

Several attempts have been made to obtain a satisfactory substitute for the lime cylinder for optical projection with the oxy-hydrogen flame. Drummond himself used magnesia, and some sixteen years ago magnesia pencils were a commercial article in Austria and Germany, and Dr. Eder has spoken very favourably, not only on account of their cheapness but also on the character of the light, which is extremely white and very rich in the blue and ultra-violet rays. Caron, of Paris, stated in 1868 that magnesia gave much better light than the lime, but that it was extremely important to free it from any trace of silica, which reduces the brilliancy to one-third or less. Quite recently the Königlichen Porzellan Manufaktur have placed on the market tubes, crucibles, and other forms of pure fused magnesium oxide. Messrs. Goodwin and Mailey were induced to try and make some of this fused magnesium oxide, and in the current number of the "Physical Review" they give some information about this new material, which leads one to suppose that it might be found useful as a substitute for the lime. It is a pure white, an very hard crystalline substance, with a surface like glazed porcelain. The approximate melting point is 3,470° deg. Fahr., which is quite high enough to do away with any trouble of this kind in the oxy-hydrogen flame, the temperature of which does not probably exceed 2,700° deg. C., and is more likely to be much less. Further, as the fused magnesium oxide is practically only attacked by the alkalis and dilute inorganic acids, it should do away to a great extent with the trouble from damp to which, as everyone knows, the lime is so prone.

### Government Support for Science.

One of the most striking features of Professor Ray Lankester's Presidential address to the British Association last week was his attack on the English Government generally for its lack of support of science. As he said, it is, unfortunately, true that the successive political administrators of the affairs of this country, as well as the permanent officials, are altogether unwary to-day, as they were twenty-five years ago, of the vital importance of the knowledge which we call science, and of the urgent need for making use of it in a variety of public affairs. Whole Departments of Government in which scientific knowledge is the one thing needful are carried on by ministers, permanent secretaries, assistant secretaries, and clerks who are wholly ignorant of science, and naturally enough dislike it since it cannot be used by them, and is in many instances the condemnation of their official employment. Possibly, Professor Lankester's remarks were all the stronger in that he has just been asked to resign his Directorship of the Natural History Museum at South Kensington.

### Made in Germany.

A great contrast is shown when the state of affairs is considered in Germany. There the State does support science to a large extent, and it is now reported that the Government has decided to establish a sort of secondary school, which shall be intermediate between the primary and those of the technical high school class, as at Charlottenberg, and it is further stated that in these intermediate

tools a study is to be made of photography as applied science. We may possibly yet see such a thing as a Governmental School of Photography set up in England, particularly if the recommendation of the Motor Traffic Committee be adopted, that all drivers' licences must bear the owner's portrait, and that this is to be furnished free of charge! Still, as the money will have to come out of the taxes, some photographers may object to pay for the head that is taken out of their mouths, and we may have another class of passive resisters.

\* \* \*

**Photographing Fortifications.** A short paragraph which we published a fortnight ago serves to illustrate how matters may, quite unwittingly, incur considerable inconvenience to themselves, if not get into very unpleasant trouble. The case was this. There was a Sunday School excursion from London to Sheerness, and seven youths of the party walked along the front of the fortifications. Two of them carried cameras, and snapshotted a couple of war vessels, and were noticed by the soldiers on duty, who forthwith took them into the garrison and afterwards to the police-station, where their plates were examined. It is not stated whether the plates were developed, but it is said that it was found that no photographs of the fortifications had been taken, and that inquiries showed that the youths had no intention of infringing the regulations against photographing defences. They were then not further detained, but the plates of the two warships were confiscated. We call special attention to this incident in order to caution photographic tourists against carrying cameras in the vicinity of fortifications, or snapping war ships, interesting as the latter subjects may be; for it is by no means pleasant for those who are out on a day's holiday, as in the case of these youths, to have to stand, say, a couple of hours of the time in the way these fellows had to do. The regulations with regard to taking photographs of fortifications here are pretty stringent. Many persons are not aware that there are any at all, but they are not nearly so strict as they are in most places on the Continent, particularly on the Franco-German frontier. Several English tourists have been arrested and been kept in practically "durance vile" for the entire day, or more, or until it has been proved that they were not spies, and had no evil intent. In some instances the inconvenience has been intensified by the tourist speaking the language of the country, and failing to give a clear explanation of the facts. In most Continental countries passports are not now necessary, but our advice to photographic tourists on the Continent is to be provided with one. The possession of a passport, of course, will not prevent the holder from unwittingly getting into trouble, but it will very materially assist him out of it by proving his identity as a British subject.

\* \* \*

**Carbon Prints on Glass.**

An American contemporary refers to the production by a Tennessee photographer of carbon prints on glass. The idea is by no means new, as on several occasions we have seen exhibition walls interior photographs produced in this way, and the method has been described in the journals. We think, however, that such prints might well be introduced by carbon workers, and if carefully handled might prove an attractive novelty. Briefly the method consists in coating a good quality of glass, probably one of the cheaper qualities of patent plate, with a bichromated gelatine substratum in the same way that transference glasses are prepared for the carbon process. The carbon print is transferred to this glass after the substratum has dried and been rendered insoluble by exposure to light, and is

developed, rinsed, alumed and washed in the ordinary way. Held up to the light such a print is, of course, very thin, but when dry if laid film side down on a sheet of paper the effect is that of a perfectly flat-surfaced, enamelled print with rich gradations and shadows and pure high lights, assuming, of course, a good carbon positive. The advantages of the method are, single transfer from ordinary negatives, the print being viewed through the glass being non-reversed; freedom from injury by scratching; and the possibility of using any kind of backing up paper, rough or smooth, white or tinted. Harsh lights may be toned down by laying a wash of colour on the backing-up paper. Such prints may be sent out bound up in the passe partout method or placed in neat and inexpensive frames if the price must be kept moderate.

## THE PHOTOGRAPHER'S WINDOW.

### I.

AMONG professional photographers there appears to be considerable divergence of opinion regarding the advisability of advertising. We think, however, there can be no two opinions about the value of at least one means of publicity—namely, the shop window or showcases. Nevertheless, these important matters do not always receive the care and attention that one might naturally expect should be invariably expended upon them. Few photographers, in fact, understand the subject of window dressing as well as most drapers, grocers, or other trades not usually associated with artistic feeling. And window dressing, or rather, successful window dressing, depends upon the same fundamental principles as all matters of good taste, music, decoration, or artistic personal adornment. There must be no harsh clashing of discordant contrasts, nor mere repetition without variety. Above all, exact geometrical forms are not to be encouraged.

Probably the number of photographers possessing windows and those possessing showcases only are evenly divided, but in most classes of business, more especially in towns, the window man is most to be envied, not only because of the relative importance of the display he can make with judicious thought, but also because a constant change of at least small features is more easily made. And this constant change is in most cases the first secret of successful exhibiting, apart from the arrangement or work shown. In any town of standing population, where probably the same people pass day after day, and probably most of the ladies of the place manage to come once or twice a month, the importance of rapid change cannot be over estimated, and the policy is bound to tell more than other forms of advertisement, always supposing that you do sufficient good work to keep up this repetition without having to fall back on your mediocre stuff to fill up.

These remarks *re* change apply also to showcases, on which we have some notes to appear in a later issue. Now we will only stop to mention one point that costs nothing, yet is more neglected than the obtaining of expensive trappings. It is to keep windows or showcases always scrupulously clean. Do not allow old specimens, sometimes faded and rain-stained, to remain on exhibition, to the detriment of every other photograph shown, as well as of your reputation. Perhaps showcases are the most neglected in this respect. Some that we have seen have been more a reason *against* visiting the studio advertised than anything else. Remember, cleanliness, smartness, and polish on even the most unassuming cases and work carry more weight than elaborate and tawdry hangings, or dirty and bedraggled specimens of the most ambitious type.

The shop window is often considered more trouble than it is worth rather than an excellent means of publicity, and the show reflects the feelings of the proprietor, for from first to last is cannot be doubted that some little thought must be expended upon the subject. As to the design of a shop window to be built or purchased, there are many questions:—Whether door at side and one large window, door in middle and two windows, or one small and one large window; distance glass is to come within reach of ground; the height the glass is to be carried; what kind of flooring within window and above; what description of partition between shop window; whether from ceiling to floor or from floor to some intermediate point, and whether of wood, glass, or flexible material.

Most of these questions will be determined by local circumstances, and, of course, if the window is already built the existing arrangements can usually be adapted to meet requirements. We are rather inclined to prefer a double window to a single one for photographic purposes, though we know that with many trades the reverse holds good; but large windows are apt to be a bugbear to photographers, and moreover the double window serves to divide up the show into more compact groups, in the same way as the stencilling or panelling at an exhibition, so that distinct and separate styles of work can be shown without discord. However, each to his taste. The height of the inside of the window should not be so low as now appears to be fashionable for shop windows, for photographs are not intended to be looked at from above, and more especially at an angle. Neither, we think, should the window extend too far back, firstly, because the finer details of the posterior pictures would be lost, and secondly, because it is obviously foolish to put one photograph dead in front of another, so to all practical purposes

one plane would be sufficient. Moreover, nothing worse than numerous niggly small cabinets spread a window to fill up, and usually obscuring one another.

With regard to the partition—and there always should be one, for it is impossible to view pictures without background of some description—in all cases where is not a skylight over the shop a space must be left the partition to illuminate the shop, or a wooden partition with glass top may be used. In any case, the portion should be at least six feet high, so that the large and smaller pictures shall have the background, not so important in the case of big enlargements or paintings. A heavy brass rod with plain self-coloured dark curtain hung upon it is good, cheap, and handy, but a paneled wood partition extending to the roof, with the top glazed with leaded glass, is effective. In this latter case the woodwork should harmonise with the general tone of the decoration—the same may be said in the case of curtains, dark green and dark brown forming a most restful background. If the bottom of window is cloth-covered it should be exactly the same colour as the curtains, in case of woodwork, of harmonising colour. These details must be quiet and subdued, and not detract from pictures exhibited either by lightness of tone or contrasting.

A very good material for floor covering is a self-coloured cork carpet. These can be got in any colour, will wear well, and moreover have a matt surface. Another good idea is to have the bottom covered with parquet flooring in dark tones. This can, of course, be covered with other material when necessary. However, enough has been said about the actual window, and we hope in a future paper to be able to say a little about the arrangement of the pictures.

## THE TONING OF BROMIDE PRINTS.

THE obtaining of warm tones on bromide paper by means of toning processes has been very much to the fore of late. A good deal has been written on this subject, but so far but little has appeared in English but what may justly be described as a mere repetition of, or modifications of, old formulæ and old sayings. Of actual experimental work from the scientific point of view there has been practically none. It is all the more refreshing, therefore, to come across a work\* which attempts to treat the subject from the purely experimental point of view, and in which statements are corroborated by experiment.

The ordinary hypo-alum toning bath, it is pointed out, depends for its activity upon nascent sulphur; but that the decomposition of hypo by an acid, although giving rise to the same reactions practically, will not act efficiently. The suggestion is that the decomposition of the aluminium hypo-sulphite plays an important part.

As regards the toning processes containing ferricyanides, the primary action may be the formation of potassium and silver ferrocyanides, and then the formation of an insoluble ferrocyanide of a heavy metal, such as uranium, or the silver may act directly on the ferricyanide of the heavy metal and reduce it to ferrocyanide, and this, apparently, the author favours as the more correct assumption of the two. His reason for accepting this view is that if metallic silver in powder form is treated with a 0.1 per cent. solution of ferricyanide of potassium, after some minutes some unreduced ferricyanide can

always be detected. If, on the other hand, the theoretical quantity of uranium nitrate be added to the ferricyanide and allowed to act on the silver, then the decomposition is momentary, so that after a brief shake neither ferro- nor ferricyanides can be found in solution.

In connection with uranium toning it is pointed out that the gelatine and paper must be taken into consideration, especially the former, as it forms a compound with the uranium which is insoluble.

The explanation of the action of the uranium toning according to the author, as follows: When a solution of uranium nitrate with potassium ferricyanide acts on silver which is embedded in gelatine, at the commencement of toning the uranium combines with the gelatine, whilst the ferricyanide diffuses through the film, and forms with the image the ferrocyanides of silver and potassium. The potassium ferrocyanide thus formed combines with the uranium-gelatin to form ferrocyanide of uranium, or enters into actual combination with the gelatine compound.

The final result may be that the uranium ferrocyanide is formed, not on the image, where it is wanted, but in the gelatine, and the silver ferrocyanide only partially reacts with the uranium ferrocyanide and gelatine compound in the course of time, and this may probably be the cause of the instability of uranium-toned prints.

Naturally, one wants a salt which will prevent the formation of this uranium-gelatin compound, and the most useful ordinary ammonia alum, for the latter forms a compound with gelatine which is not acted upon by ferro- or ferrocyanide.

\* Die Tonungsverfahren von Entwicklungspapieren, by Dr. E. Sedlacek. Published by Wilhelm Knapp, of Halle.

however, alum also stops the toning action, it is necessary add an acid which restores this without giving rise to the uranium-gelatine compound, and hydrochloric acid is the best. In order that the baths shall keep, it is necessary to use certain organic acids or their salts, and potassium oxalate will be found one of the most satisfactory. In fact, a bath composed of uranium nitrate, potassium ferricyanide, alum, and oxalate has practically no toning property, and hydrochloric acid or some other highly ionised acid is required to take it tone.

The author, then, on his experiments, which are but briefly abstracted above, gives the following formulæ for obtaining various tones:—

#### DEEP BROWN TONES.

Uranium nitrate, 10 per cent. sol. ....	50 minims.
Potassium ferricyanide, 10 per cent. sol. ....	20 minims.
Potassium oxalate, 10 per cent. sol. ....	50 minims.
Hydrochloric acid, 10 per cent. sol. ....	10 minims.
Water to .....	2 oz.

#### WARM BROWN TONES.

Uranium nitrate, 10 per cent. sol. ....	50 minims.
Potassium ferricyanide, 10 per cent. sol. ....	20 minims.
Potassium oxalate, 10 per cent. sol. ....	50 minims.
Ammonia alum, sat. sol. ....	100 minims.
Hydrochloric acid, 10 per cent. sol. ....	3 minims.
Water to .....	2 oz.

#### BROWN TONES.

Uranium nitrate, 10 per cent. sol. ....	50 minims.
Potassium ferricyanide, 10 per cent. sol. ....	20 minims.
Rochelle salts, 10 per cent. sol. ....	70 minims.
Tartaric acid, 10 per cent. sol. ....	10 minims.
Water to .....	2 oz.

#### REDDISH BROWN TONES.

Uranium nitrate, 10 per cent. sol. ....	50 minims.
Potassium ferricyanide, 10 per cent. sol. ....	20 minims.
Rochelle salts, 10 per cent. sol. ....	50 minims.
Ammonia alum, sat. sol. ....	100 minims.
Tartaric acid, 10 per cent. sol. ....	50 minims.
Water to .....	2 oz.

It is not advisable to use the baths too long or for too great an area of paper, and  $3\frac{1}{2}$  oz. should suffice for about 700 square inches.

If the prints, no matter what bath they are toned in, are treated for five minutes to

Sodium sulphide .....	$2\frac{1}{2}$ grains.
Hydrochloric acid .....	1 minim.
Water .....	2 oz.

they assume a deep brown tone, and will keep for at least four years without any change or bronzing in the shadows.

#### Iron Toning Processes.

In the iron toning baths there are always two salts which can act on the silver image, namely, potassium ferricyanide and ferrous salt. The silver reduces the ferricyanide to the ferrous state, and this combines with the ferric salt to form Berlin blue, or ferri-ferrocyanide. If it is assumed, independently of the probability of ferri-ferrocyanide existing in the solution, that the ferric salt is reduced quicker to the ferrous state than the ferricyanide of potassium, Turnbull's blue, or ferri-ferrocyanide is formed. If the two salts are both reduced at the same rate, then a white salt, the ferro-ferrocyanide, is formed.

The ferric salt used throughout by the author is ammonia iron alum, which is cheap, and a perfectly stable ferric salt.

The colour obtained with ferricyanide and a ferric salt is

an unpleasant dead blue, and the whites are usually stained through the precipitation of basic iron salts. The addition of an acid improves the bath in both ways.

An excellent deep blue tone is got, which can hardly be obtained in any other way, by bleaching the print first in a 5 per cent. solution of potassium ferricyanide with the addition of a little potassium oxalate, well washing, and then bathing in a 2 per cent. solution of ammonia iron alum, to which some potassium bromide and hydrochloric acid are added. The chemical action may then be thus expressed:—

In order to decrease the action of the toning baths oxalic acid is the only one that can be used, and potassium citrate, Rochelle salts, and the oxalates may also be used—in the above order, as regards efficiency in this respect.

Iron combines with gelatine in the same manner as aluminium and uranium, but rather less than the latter; it is advisable, therefore, to use alum in all the iron toning baths, and also an organic acid, to prevent the precipitation of basic iron salts in the gelatine and the paper.

The images toned with iron baths contain, with some unaltered silver and ferri-ferrocyanide, also some silver ferri-ferrocyanide, which only reacts very slowly with the iron complex; but this is easily decomposed by subsequent treatment of the prints with a solution of a ferric salt containing potassium bromide, alum, and an acid. This gives bluer tones.

The following formulæ are given to obtain various tones:—

#### A DEEP BLUE TONE.

Ammonia iron alum, 10 per cent. sol. ....	12.5 minims.
Potassium ferricyanide, 10 per cent. sol. ....	10 minims.
Potassium citrate, 10 per cent. sol. ....	10 minims.
Ammonia alum, sat. sol. ....	50 minims.
Hydrochloric acid, 10 per cent. sol. ....	2.5 minims.
Water .....	1 oz.

The citrate of potash may be replaced by 3 minims of saturated solution of oxalic acid.

#### A COLD BLUE TONE.

Ammonia alum, 10 per cent. sol. ....	50 minims.
Potassium ferricyanide, 10 per cent. sol. ....	10 minims.
Potassium oxalate, 10 per cent. sol. ....	30 minims.
Ammonia iron alum, 10 per cent. sol. ....	12.5 minims.
Hydrochloric acid, 10 per cent. sol. ....	2.5 minims.
Water .....	1 oz.

In place of the oxalate, 15 minims of a 10 per cent. solution of Rochelle salts may be used.

#### A GREY BLUE TONE.

The same bath as the last, but with 5 minims of a 10 per cent. solution of tartaric acid instead of the alum, and without the hydrochloric acid.

#### A BRIGHT BLUE TONE.

Ammonia iron alum, 10 per cent. sol. ....	50 minims.
Potassium bromide, 10 per cent. sol. ....	30 minims.
Hydrochloric acid, 10 per cent. sol. ....	5 minims.
Water .....	1 oz.

By treating prints toned in the above baths with a .01 per cent. solution of carbonate of soda or ammonia, reddish-violet tints are obtained, and greenish-blue to green tones by immersing them in:—

Sodium sulphide, 10 per cent. sol. ....	0.5 minim.
Hydrochloric acid .....	0.5 minim.
Water .....	1 oz.

Care must be taken not to leave the prints too long in this, or they will turn black.

(To be continued.)

## CHARACTER LIGHTING AND POSING.

It is not unusual for one to see pictures that would be of the very first order if it were not for the fact that the operator used poor judgment in the distribution of his light over the face, says Mr. Felix Raymer, in the "Photographic Times." It is a well known fact among the best workmen that the expression is controlled in no small degree by the arrangement of the shades on the light, and the strength of the light as it falls on the face. The expression of a face is nothing more or less than the lines showing in the faces of some subjects differently from others. We look at one face and say the expression is good, or bad. We mean by this that the expression is either pleasant or otherwise. The cause for these differing expressions is that certain faculties in the face and head have been used by one person, while others have been used by the other person. The one having a pleasant expression has brought into play faculties that form different lines from those brought into play by the person having a sour expression. These lines will be shown in each face more or less regardless of what the operator does, but there are times when he may soften them and make a better expression. It will not be possible to take them out entirely, and neither would it be the part of wisdom to do so. If they are taken out we destroy the likeness, but we may soften them and it proves an advantage.

### Concentration.

Before going into the matter of diffusion and concentration, I would like to have it understood that I make either the soft diffused or strong concentrated effects the same so far as the direction the light takes in falling towards the subject is concerned. In fact, all effects of light should be made the same up to the point where we decide there should be a softer effect made. If this is done all that is left to do will be to place a white screen over the head. It has been my observation that many operators do not know what shade or colour curtains or screens to use to secure the different effects. I have found on most lights two sets of curtains, one that had at one time been white, but is now a dirty yellow, or some other tone that is not desirable, and the other set of some darker tone, say a blue, drab, or similar nature. Now, I have found that the simpler we can curtain the light the better off we will be and the easier we can get what we want. It is all right to have the two sets of curtains, but first understand what each set is to do. One set will do for one thing while the other is for a different purpose altogether. We know that we want diffusion or softness at times. Now the natural question would be what shades or curtains will produce this softness. There can be one answer to that question, and that is "a curtain that will soften the light but not close it out of the room." There can be but one curtain that would do this, and that would be white. Now, do not think because the curtain was white when it was first placed on the light that it will do for ever and eternally. It will not, for it catches dust, and if the light leaks, which is more than probable, it will have dust streaks all through it, and after a time it becomes a dirty yellow or brown. When this stage is reached it closes out more or less of the light, which is quite a different matter from diffusing it, or making the effect softer. The more colour there is to the shades of curtains the more of a concentrated effect will result where the shades are used. For diffusion the light should not be made smaller, nor any part of it closed out, but all of the light should pass through white screens or sifted through. The effect of this can be seen by looking into the dark corners of a room, while the light comes through a window, which has not been covered with a screen. Then take a white screen and place over the window, and see the dark corners become higher illuminated, with greater detail in them. Now comes the question, "But if the light is screened in this way will it not make the exposure longer?"

### Opaque Curtains for Concentration.

No, but the reverse. It makes it necessary to give somewhat less time than where the stronger light is used. Remember we are to time for the shadows. When the light is open the dark corners (or shadows) are so deep that there is but little or no detail in them. But when the white screen is placed over the windows the shadows become more luminous and full of detail. When this is done the

time which is still for the shadows may be less, for it is for that we expose, and if the shadows are lighter we require less to get the detail. So much for diffusing curtains. for the concentrating curtains. We all understand to concentrate means to close up, to make smaller, to eliminate certain things and accentuate others. How is this to be done? There can be but one way to concentrate the light on any part of the face and that is to make the part small enough to allow its falling on that part of the face, and nowhere else. Now, is this to be done? Why, by making the light smaller and moving the subject up closer to it so that the light will not spread all over the subject. There can be but one way to make the light small and that is to close off part of it. This can be done only by having curtains that are absolutely opaque, so that no light can get through them. When such curtains are drawn over any part of the light that part of the light is closed out of the room, and, of course, the remaining part is smaller, and, being smaller, it concentrates at some particular part of the face. There is the success of concentration. Now, if the operator understands the uses of these two classes of curtains he will have no trouble in securing the effects he is after. I have found many operators who think they are closing off the light when they draw a white curtain over the light, while others think they are making the effect of light softer by drawing an opaque curtain over the light. These are both wrong. If the soft effect is wanted use the curtain that will make the light soft—white. If a concentrated effect is wanted use the opaque curtain that will concentrate the light, which is, of course, opaque curtain. I use very dark green on my light for the opaque curtains, and find them very satisfactory.

### Management of the Lighting.

In making up the lighting for each face, there should be a careful study made of all faculties which go toward making up the character of that face. It is found that the face has a very decided marking of character. It will likely be to the advantage of the subject to have this character modified or softened. If so here is where the white curtains come into play. But, on the other hand, if the character is found rather insipid and weak it will likely be to the advantage of the subject to concentrate the light more and accentuate the character that is shown still stronger. I will suggest my plan of procedure, and those wishing to try it are welcome. First, I have the subject seat himself under the light at whatever point the posing chair happens to be. It is, of course, at different stations in the room, owing to the fact that on one subject I had to concentrate the light more and in doing so had to place the subject nearer to it, while in another case I wanted a softer effect, and placed the subject farther from the light, opening all of the opaque curtain, and softening the effect with the diffusing curtains. Therefore I say seat the subject at whatever point the chair happens to be. Next, arrange the light so that it falls on the face from an angle of about 45 degrees. To do this quickly all that is necessary is to notice the shadow from the nose, and when it falls away from the nose towards the corner of the mouth the light will be about right. Next have the subject turn towards the light until there appears in the shadow eye a small dart of light, known as the catch light. When this point is reached have the subject rest for a moment or so while you study the lighting. If the lines appear abnormally deep it is because you are using too concentrated effect of light. Move the subject farther from it and arrange it again so that it falls on the face from an angle of 45 degrees. And I will say here that the direction the light falls is controlled entirely by the arrangement of the opaque curtains. The white curtains are to soften the light, remember. After the opaque curtains have been drawn so that the shadow from the nose falls towards the corner of the light, and the catch has been secured, notice the lines of the face again. If they are still too strong move him farther from the light and proceed as before, but if they appear about what is natural next look at the deepest shadows and likely they will be too deep for the highest lights. If so, draw the white curtains until they come together in better harmony.

If when the subject is first seated the light seems too soft or flat, move the subject nearer the light and concentrate it more, or, in other words, make the light smaller. This will have to be done in every case if the right direction of light is secured (45 degrees). But

there will be little trouble if the nature of the two sets of curtains is understood. The opaque for concentrating and controlling the direction of light takes in falling on the face, and the white for softening that light after the direction of it has been secured.

## THE BASIS OF THREE - COLOUR PHOTOGRAPHY.

(Translated from Das Atelier.)

Continued from P. 491.

The fundamental colours which three-colour photography must use, and what the difference is between the physiological and the artists' primaries, can be easily determined from what has already been said, and from the diagrams of the colour circle. The three colours which are symmetrical as regards the centre, form the artist's primary colours, for it necessitates as far as possible equal purity of all the compound colours, and the equilateral triangle includes the greatest possible area.

It may possibly appear that the arrangement of the colours on the circle is to some extent permissible, and dependent to a great extent on the subjective sensation. This is, however, not the case. First of all, Hering's fundamental colours are arranged at four points, which must be 90 deg. from one another, and which can be determined with tolerable certainty, and can be objectively prepared, which is not the case with the Young-Helmholtz primaries.

If we think of, according to Hering (\*), a series of colours which gradually merge from yellow through green into blue—that is, which correspond to the yellow and blue parts of the spectrum, there is something common to all except the end members of the series: that they all contain green. The pure green, however, is a distinctive point in the series, in so far that it is different to all the colours on one side, as it contains no yellow; also it differs from the colours on the other side in that it contains no blue. It corresponds, therefore, to the position in the series where the admixture of yellow is wanting, and where the admixture of blue is not yet recognisable. For this sensation, therefore, which contains neither blue nor yellow, we give a special name; for we cannot talk of a yellowish blue nor of a bluish yellow, for we not only cannot see in it these two colours once, but not any of them. The relative simplicity of this green sensation, compared with the two-colour composition of its neighbours, gives it a distinctive place in the above series of colours.

There are three other colours besides this green, namely, red, blue and yellow, which can occur without any tinge of any other colour. Red and green, and on the other hand, yellow and blue, can never be seen in a colour; they shut one another out, and were thus called "Opposing colours" by Hering, a term which he preferred to the usual term, "complementary."

These four colours, which obviously have nothing to do with the physiological primary colours of Young-Helmholtz, and which should not be confounded with the latter, may be easily obtained by the aid of a series of coloured papers or transparent films. They form, as already stated, four definitely determined points in the colour circle. The correctness of the choice of the colours may be determined by means of colour-top sectors; for red and green on the one hand, and blue and yellow on the other, should combine to form white. But the four quadrants must be filled with intermediate colours, which is rather difficult.

There is no doubt that midway between red and yellow must lie an orange, which shall equally excite the red and yellow sensation; but this cannot be accurately determined, for the regions of the sensation red-orange and orange-yellow are too great. The estimation of this mean orange by mixture of equal parts of red and yellow is also not permissible, as it is questionable whether the chosen colours are of equal colouring power—that is, of equal saturation. With the aid of the colour circle, red and green, and also the blue and yellow, may be chosen so that they are of equal saturation; thus, that when mixed in equal quantities they produce white; whether, however, both pairs of colours will satisfy this requirement, is questionable. A tolerably satisfactory way to attain this end is, however, the

following: If three colours,  $a$ ,  $b$ , and  $c$ , on the periphery of the circle—thus, of equal saturation—form white, they must be symmetrically divided, and the centre of gravity of such a triangle must be in the centre,  $O$ . If, however, instead of  $b$  a colour  $b^1$  is chosen, which is about 20 degs. to one side, white will not be formed by the admixture, but a whiteish violet corresponding to gravity point  $s$ , of the system  $a$ ,  $b^1$ ,  $c$ . If white, however, is to be the result, the saturation of  $a$  and  $b^1$  must be reduced; instead of the saturated colours mixed with white, the shades lying on the radii  $a\ o$  and  $b^1\ o$  be used. Putting it mechanically, the weight from  $a$  and  $b^1$  must be shifted along the radii to  $a/b$  so that the centre of gravity of the new system falls at  $O$ . A mixture of 0.6 of saturated blue with 0.4 of white, corresponds, as shown by the figure to the blue at  $a^1$ , and since the brightness as already mentioned is perceived in logarithmic progression, this blue makes far too white an impression; it appears too bright, just as though it were formed of 0.8 of white and 0.2 of blue.

From these considerations it will be seen that three colours which do not lie symmetrically can only form white or a neutral grey, when the saturation of one or other of the colours is lowered to a very great extent. And, inversely, it may be said, that when three colours, which appear equally saturated and pure, are mixed in equal parts in a colour top, and give a neutral grey, then it is a sign that they approximately lie symmetrically on the colour circle.

Such mixing experiments offer a ready means of the choice of three colours which are symmetrical, for if we choose from a number of apparently equally saturated colour papers, three, which, when mixed in sectors of 120 deg. on the top, give a grey, their colours answer to the above requirements.

By choosing an ultramarine blue, a vermilion red, a yellowish green, and a yellow which is as saturated as and complementary to the blue, any desired shade may be produced on a colour top. For instance, if the blue and yellowish green are mixed, a blue green will be obtained which is complementary to the vermilion red; that is, at the other end of the diameter drawn from this red; from equal parts of this red and blue crimson will be obtained that lies midway between them.

The next point to consider is how the colours are to be split up by photography. Every colour has to be divided into three colours—the artist's primaries—by suitable plates of filters. On each plate must, speaking generally, two of these colours be reproduced bright, like white, whilst the third must be inactive like black. This is obviously only possible when each two colours have a range of spectrum colours in common, which are wanting in the third. In the spectrum there are, however, present almost only red, green and blue rays, and by these the colours of the substances are actually produced, whilst the intermediate colours, yellow, blue-green and violet, scarcely play any part. An object, for instance, appears yellow or blue-green, because it principally reflects green and red, or green and blue rays. In the photographic splitting up of the colours these rays need alone be considered.

If we imagine a colour circle composed of pigmentary colours, and determine those zones which reflect the above-mentioned spectrum rays, we obtain a diagram as in Fig. 4. It must be remembered that violet and purplish red pigments are produced by the red and violet rays, and that every pigmentary colour which has the same hue from the spectrum red to a vermilion of  $\lambda\ 600$ , and every colour from the spectrum violet to ultramarine at  $\lambda\ 460$  are indebted for their colour to the mixture of spectrum red and blue.

The three colours which are symmetrical, and which in photography answer to the above requirements, can only lie in the points,  $a$ ,  $b$

\* E. Hering, "Die Lehre vom Lichtsinn." Wien, 1878.

and c, and correspondent therefore to the fundamental colour system, crimson yellow and blue green.

Many experiments have completely confirmed this view, for it is quite impossible to photograph any other three or only half symmetrical colours, so that two are dense in the negative, whilst the third appears like black. These experiments also prove that in the interest of a perfect colour disassociation one is compelled to keep pretty accurately to the three colours; the point *b* can be shifted to *b*<sup>1</sup>, thus instead of a neutral yellow choose a greenish yellow in conjunction with a blue of a less greenish hue, and a crimson of a redder shade.

For this reason, in all methods of three-colour photography we are limited to one fundamental system. In all three-colour printing methods the negative must be printed in the mentioned colours, and in three-colour projection the colours of the constituent images are formed by the admixture of the two projection filters. Because of the symmetry of the colour triangle, the projection filters must be complementary to the fundamental colours, and therefore ultramarine blue, vermilion red, and yellowish green. These colours correspond to the spectrum colours at wave-lengths 600, 530 and 460.

In all methods which are based on the combination of material images another fundamental system cannot be used, as yellow can-

Fig. 3.

Rot = Red. Gelbgrün = Yellowish-Green. Blau = Blue.  
Orange = Orange. Grün = Green. Violett = Violet.  
Gelb = Yellow. Blaugrün = Blue Green.

not be produced by the admixture of pigments. As, however, we have not sufficiently pure blue-green and purple-red printing inks which are stable to light, it is necessary for photomechanical printing to choose other colours. Instead of *c* we use *c*<sup>1</sup>, and instead of *a*, *a*<sup>1</sup>, whence the photographic splitting up of the colours is rendered much more difficult and is less complete. As to other disadvantages caused by the non-symmetry of these practical methods we cannot here enter upon.

It is interesting to compare the above described symmetrical colour system with that of the physiological fundamental colours.

Dr. Donath assumes, for instance, that the fundamental colours of the Young-Helmholtz theory correspond to the extreme limit of the visible red, in the green to  $\lambda$  507 and in the blue to  $\lambda$  475.

If these colours are plotted out in the colour circle we obtain the triangle *a, b, c*, for the spectrum red is yellower than Hering's red; the green may be considered as a pure green, and the blue is somewhat greener than the pure blue. That the position of the colours must be correct is seen from the fact that the complementary colour to the extreme end is about  $\lambda$  494, and does not thus therefore differ much from the chosen green.

If the colours are equally saturated they give, when mixed, a whitish blue, for the centre of the triangle, *a, b, c*, lies at *s*. If these three colours are to be used as chromoscope filter colours, the saturation of the blue must be so lowered that the shade corresponds to the point *a*<sup>1</sup>, then white will be obtained from *a, b*<sup>1</sup>, *c*, for the centre lies at *O*. The colour of the constituent images will then be the result of the mixture of two filter colours, and will correspond to

the point *m, n, p*, or *M, N*, pure red (carmine), *N*, greenish yellow, *P*, blueish green.

Independent of the very unhappy form of the mixture triangle, splitting up of the colours of the original into such components is quite impossible, for one cannot photograph carmine red and green like white, and at the same time greenish yellow like black.

As a matter of fact in practice, the physiological fundamental colours are never chosen for the reproduction filters, but colours

Fig. 4.

used which experience proves correct, and which approximately correspond to the above-mentioned system. This is at least the case in a Miethe chromoscope which the author possesses.

Finally, it may be remarked that it is quite impossible to split the colours of an original into four fundamental colours. If, for instance, Hering's four fundamentals are chosen, blue, yellow, green, and carmine red, a glance at Fig. 4 will at once show that it is not possible to obtain a negative in which three colours will act like white and the fourth like black, for it is, for instance, quite impossible to obtain green brighter than yellow.

#### Additive and Subtractive Filters.

From the above considerations it ought to be clear that with processes of colour photography, that because it is essential to

Fig. 5.

the same fundamental colours, the same filters must be used for the negatives, and thus a difference between the additive and subtractive filters is not correct.

If we had suitable dyes the material images—as shown above—would combine according to the same laws as the optical images, at it is not apparent why the constituent images of the same colour should be of different quality. This, however, does not exclude the fact that in practice the intensity of filters must be altered, in order

influence the colour gradation of the negatives, exactly as in black and white photography the character of the negative is altered to suit the printing process.

If, however, the fundamental colours are altered, then the content pictures must be altered and the filters modified.

This is the reason why in three-colour printing—for which the symmetrical colour system cannot be used—other filters than those used for three-colour projection. The expressions, "additive" and "subtractive" filters are not happy, for this leads one to conclude at the necessity of having two different kinds of filters is due to the essential difference between additive and subtractive colour mixtures. Perhaps the terms, "three-colour print" and "three-colour photograph" filters would be better.

As regards the colour of the taking filter it should be first noted that this may differ considerably, and yet equal results be obtained, in the spectroscopic behaviour of the filters must be adjusted to the plates. A yellow filter, as is well known, may give the same results with an erythrosine plate, as a green filter with a pinachrome plate.

Fig. 6.

With panchromatic plates, on the other hand, the colour of the filter must be very closely allied to the fundamental colours. Let us take a white surface, F. Fig. 6, on which are painted a series of colours of equal saturation and purity, and so that the succession of colours falls as in the colour circle, and let A be the yellow-green filter interposed during exposure; if the latter is correctly made the negative N will be shaded off on each side of the yellow-green. The taking filter must be so made that the yellow-green colour, *a*, acts like white; red, orange-red, blue-green and blue pigments must act like black, and the pure green and yellow be reproduced with half the intensity of the yellow-green. According to the law the colour mixtures, the filter will have a yellow-green colour as at *a*, and the negative will correspond at that place to the proportion of yellow-green in the pigment.

The taking filter A is thus complementary to the fundamental colour.

If from this negative a transparency P is made and projected through a green screen R, there will be formed on the screen S an

image corresponding in gradation to the negative in the colour of the filter R.

If this image is to represent the proportion of green in the pigment colour, and thus serve as one of the constituent images in the reproduction, it must correspond in colour to the green photographically isolated from the pigment colour—that is to say, the projection filter R and the taking filter A must be of the same colour.

It does not follow from this that the two filters can be changed one with the other. For independent of the different saturation the taking filter must have certain definite spectroscopic qualities, whilst in the projection filter the hue alone has to be considered.

Many have tried to derive the colour of the taking filters from the Young-Helmholtz colour theory, and enunciated the law that "each of the three taking plates excites one group of nerve fibrils, the filters must therefore be so chosen that they transmit the rays of the spectrum in the intensity ratios of König's primary sensation curves." These curves are shown in Fig. 7. They express the intensities in which the very saturated fundamental colours, red, green and violet

Fig. 7.

must be mixed so that the sensation of the spectrum colours must be produced. The curve R corresponds to the intensity ratios of the red; the curves, G and V, the intensities of the green and violet fundamental colours.

If the above views are followed it is determined that the ordinates corresponding to each spectrum colour is the measure of the transparency of the filter. If the transmitted spectrum rays are mixed, the colours obtained will be the colours of the filters. The red curve R corresponds thus to a filter, which principally transmits yellow, orange and yellowish-green light, less red and green, but some blue-violet. The colour of this filter will therefore be a brownish yellow, for pigments only appear pure yellow when they reflect or transmit the whole of the spectral green and red.

Such a filter may be easily obtained by mixing a solution of acridine yellow and naphthol green. It is obviously absurd to use this filter for trichromatic work, for even with a perfect panchromatic plate it would give perfectly useless results. This observation again shows that the Young-Helmholtz theory cannot be satisfactorily employed in three-colour work.

## SPECTRO AND COLOUR SENSITOMETRY.

### A SUGGESTED METHOD OF COLOUR SENSITOMETRY.

SEDDIG, in the "Zeitschrift für Wissenschaftliche Photographie," writes:—

Newton's colour triangle is usually projected by means of three triangles in the fundamental colours red, green, and indigo blue, and superimposed on the screen so that each triangle shades off from the apex to the base, and so that the maxima of brightness for each colour lies in a different corner of the triangle.

Experiments to obtain a perfectly continuous and, for each triangle, equal gradation of brightness, present considerable difficulties, for either shaded transparencies nor wedge-shaped troughs filled with dye solutions and placed in front of each triangle, gave satisfactory results. Rotating sectors were not used because it was found that the same effect could be obtained in the simplest and most perfect way by suitable diaphragms.

The method of diaphragming is schematically shown in Fig. 1. In the diagram *ac* is a section of a triangular diaphragm in which

the apex is at *c* and the base at *a*. In the middle between *ac* and the projections lens *O* is placed a diaphragm *B* which reaches only to the axis *m m'*. The effect of this stop is that the apex of the

Fig. 1.

triangle *c* is illuminated by the whole of the objective, and therefore with maximum brilliancy, whilst for the other parts of the triangle part of the objective is stopped out; for the centre part *m m'* of the triangle, for instance, half the lens is used, so that these parts will

only be projected on the screen with half the luminosity, till finally for *a* the whole lens is stopped out, so that there is actually no light from the base.

Fig. 2 shows an apparatus constructed on these lines. On the

Fig. 2.

### A METHOD OF SPECTRO-SENSITOMETRY.

A paper by Ed. Belin, communicated to the French Photographic Society.

ONE of the most essential of all the indispensable tests in photography and one of the most important is undoubtedly that of the sensitiveness of preparations to light, not only from the quantitative, but also from the qualitative, point of view—that is to say, their sensitiveness to spectrum lights.

The measurement of this sensitiveness has been the subject of considerable study and work, notable amongst which are the researches of the International Congress of 1889 and 1900, of Hurter and Driffeld, of Dr. Eder, and, more recently, that of MM. Monpillard and Callier.

right are the three triangular diaphragms, which are illuminated means of an arc lamp, the light of which is diffused with a gro glass screen, and each of which corresponds to *a c* in Fig. 1. To left are the three projection lenses which are adjustable towards the optical axis by micrometer screws, so that the three triangles may be conveniently superimposed. In the middle of the apparatus are the half-shadow diaphragms which correspond to *B* in Fig. 1. colour filters, which require very careful adjustment, are placed in front of the lenses.

By superposition of the shaded triangles there is formed on screen one single triangle, which shows in the three corners the fundamental colours, and includes in between the other colours of Newton-Helmholtz colour triangle. The white of the centre is very difficult to obtain, because of its small extent and the distracting colour action of the other colours.

This principle of half-shadow diaphragms ought to be applicable to other purposes, as, for instance, in the construction of a densitometer for photographic plates, the density giving powers of which to different intensities of light have to be measured. For such instrument only the part *a c* in Fig. 1 would need to be constructed with a rectangular aperture which could be perfectly illuminated with diffused light. In the position *O* in Fig. 1 would be placed the plate to be tested. With this arrangement could, for instance, be obtained in the simplest manner the decrease of density of the emulsions for different coloured lights of equally decreasing intensity.

known and always the same whatever may be the photometer standard or the ordinate under consideration.

The apparatus which we then suggested was a spectrograph fitted with a diffraction grating, in front of the collimator slit being a shutter with a sinusoidal movement.

After an exposure of 30 seconds to an incandescent lamp of 10 c.p. and 110 volts, the plate (when developed) bore one pair of reduced, the outline of which corresponded to a curve generally traced by points.

Good as this method was, and although simple and giving in

FIG. 1.—The Complete Apparatus.

FIG. 2.—Exposure Disc—Front of Collimator.

Since the congress of 1900, M. Lieut.-Colonel Houdaille has presented to the permanent commission some results of great importance, not only on the sensitiveness of emulsions, but also on developers; also a rational method of measurement and a densitometer, experience of which has proved its value.

Considering, then, as exact both this and Scheiner's method, the author does not propose to treat here of the measurement of the sensitiveness of photographic preparations to white light, nor of the standard light, which has been so well studied by MM. Féry, Fouché, and Monpillard, but simply of the measurement of the sensitiveness of orthochromatic plates by a spectro-sensitometer.

In March, 1902, we presented to the permanent committee of the International Congress a method called sinusoidal spectro-sensitometry, based on the following principle: the measurement of the sensitiveness of an orthochromatic plate, by photographing a normal spectrum unequally illuminated as to its height, the ratio of the quantity of light by two points on the same ordinate being exactly

comparable, it was objected that, without diagram the readings were difficult, for the ordinates of two points were not proportional to the corresponding times of exposure. Dr. Bin proposed to substitute for the sinusoidal shutter one pierced with an aperture in the form of a right-angled isosceles triangle, in such a way that one side of the angle was parallel to the slit.

If this shutter was set in motion, the result would be a curve somewhat similar to the last, but such that the ordinates were proportional to the times of exposure, and so that the sensitiveness could be measured, without a diagram, simply by means of a pair of compasses.

Another objection, however, now cropped up, and that was the mechanical difficulty of making an apparatus, which should have a uniform rectilinear alternating movement. It is true it could be effected with a cam, but this wears out very rapidly, and the correctness of its movement has been contested.

At the International Congress at Liège a form of shutter was

proposed, formed of a disc pierced with apertures of triangular form, and calculated in such a manner as to maintain the ratio of the ordinates to the times of exposure. A new modification has since been made.

Before the presentation of the apparatus to the congress of Liège, at the same sitting the meeting, on the proposition of M. Houdaille, repealed the rule formulated by Colonel Goulier and M. de la Baume-Pluvinel, according to which the quantity of silver reduced

Seven gradations with the base of 2 were chosen—that is to say, 2, 4, 8, 16, 32, 64, and 128. These numbers corresponding, then, to the quantities of light received by the sensitometer degrees, 7, 6, 5, 4, 3, 2, and 1 gives the sensitometer degrees in inverse ratio to the density.

The spectro-sensitometer is composed of three essential parts: (1) a standard light, (2) spectrographic apparatus, and (3) a shutter mounted in front of the slit.

*Sensito-metric figures.*

*Light ratios.*

FIG. 4.—Ordinary Gelatino-bromide Plate.

*Sensito-metric figures*

Negative from which the diagram is printed.

FIG. 5.—Ortho Plate of greater sensitiveness to yellow than to blue, and capable of being used without a screen.

on a plate is proportional, not to the absolute value of the ratio of the light received to the light transmitted, but to the logarithm of this ratio. This measure, generally called "blackness" or "opacity," received then the name of "density."

As then the sensitiveness may be accurately valued by this density, it was only logical that the divisions of our ordinates should not be proportional to the light received, but to the logarithms of the same. The sensitiveness and the density should thus to some extent be a common measure.

The source of light first adopted was the secondary standard adopted by the permanent committee, but since then an electric incandescent lamp actuated by accumulators has been adopted, as it has been found sufficiently constant. This lamp is mounted on a one-mètre slide, graduated in half centimetres.

Between this lamp and the spectrograph is placed a 10mm. cell, with parallel sides, to receive solutions for selective screens.

After some hesitation a transmission diffraction grating was chosen, the replica being mounted on a quartz plate. The two

lenses were also of quartz, the focus of the collimator 10cm., and that of the objective 30cm. In front is a parallel-jawed slit, which can be opened or closed by a micrometer screw and a graduated head.

The shutter is a disc of very thin metal pierced by two apertures cut according to the curve described above. This disc is mounted in front of the slit in such a manner that when the disc revolves the slit is completely uncovered for an instant, and then gradually closed by the rotation of the disc. The latter is actuated by a pulley or wheel of 15cm. diameter.

When the slit is completely uncovered, the spectrum is 35mm. high and 112mm. long, from A to H, and is received on a 13cm. by 18cm. plate, placed in a slide, so that the photographic image can pass the limits of the visible spectrum and the sensitiveness be studied in the infra red and ultra violet.

The method of using the apparatus is very simple. After it has been seen on the ground glass of the camera that the lamp is burning properly, and the whole apparatus is in correct adjustment, a plate is placed in the slide and the shutter set going.

As regards the time of exposure, this varies, of course, according to the light and the distance of the same; but under normal conditions and with a 10-c.p. lamp at 53cm. from the slit, the mean exposure is thirty minutes.

If the plate is then developed, the negative will give a curve, but without any indication which will enable one to read it. It is necessary, then, to impress on the plate after exposure and before development a very exact diagram exactly reproduced, indicating the principal divisions of the spectrum according to the Fraunhofer lines, and dividing its height into seven equal parts corresponding to one degree of the sensitometer. The illumination of each degree is half of the preceding and double that of the following one.

It is hardly necessary to insist on the necessary precautions of drawing this diagram very exactly, but it is reproduced by collodion. The negative thus obtained is intensified, blackened with sulphhydrate and cut to 13cm. by 18cm. so as to exactly coincide with the image of the spectrum.

To impress this scale on the plate, it is only necessary to press into contact with the plate and expose for a second to the dark room lamp. On development, the characteristic curve of sensitiveness will be obtained on the diagram.

It will be found that for the majority of orthochromatic plates there are two maxima, separated by a very distinct minimum; the action extends beyond H<sup>1</sup> with chlorides of silver, and it is very easy to determine the absorptions of selective screens. The instrument can also be used to compare different sources of light.

With regard to reading the curves thus obtained, there is one very important point to determine, and that is the tint that is to be adopted as the limit.

Dr. Eder assumes that the sensitometer degree of a plate is the last degree visible by reflection from a white surface. This was accepted, but the permanent committee of the congress has rejected it and adopted a normal grey. The new measures have made the measurement of the opacity indispensable, and this Eder refines as the ratio of the incident to the transmitted light.

Several instruments have been proposed for this purpose, such as the micro-photometer of Hartmann, Marten's photometer, and Monpillard's opacity comparator. All these instruments are based on visual examination, which gives results varying with each individual observer.

M.M. Bouasse, Féry, Precht, and Stenger use a thermopile, based on the galvanometric deviations when the opacity of the film varies between the source and the couple. This method was tried, and whilst the results were very uncertain, the author recommends this method.

Two other methods have been tried, an ingenious one suggested by M. Braun, which requires further trial, and a new one devised by the author, of which full details will be given later.

Generally, if the plates examined are to be subsequently used for practical negative work, the opacities ought always to be measured by a light analogous to that which will be used for printing. Between this light source and the plate examined, one ought always to insert a screen, only passing those rays corresponding to the maximum of sensitiveness. Moreover, the sen-

sitiveness of a plate should be indicated on the box by the manufacturer by numbers corresponding to the maximum and the wavelength of the corresponding light. Finally, manufacturers should paste on the bottom of the box a few lines in explanation of the numbers.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been applied for from July 23-28:—

FILM-DEVELOPING APPARATUS.—No. 16,706. Improved apparatus for use in developing, fixing, rinsing, and drying of photographic films. Anthony Fodor and Arthur Kitson, 11, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 16,771. Improvements in cinematograph apparatus. Henry William Joy, 3, Brown Street, Market Street, Manchester.

KITE OR BALLOON PHOTOGRAPHY.—No. 16,812. Improved method of producing correct contour maps, plans, and military positions and the like on the basis of kite or balloon photography applicable also to the production of photographic coast surveys from on board a ship. Theodore Scheimpflug, 46, Lincoln's Inn Fields, London.

DARK SLIDES.—No. 76,892. Improvements in and relating to photographic dark slides and plate-holders. Alfred Edwards Briggs, 27, Chancery Lane, London.

CAMERA ATTACHMENTS.—No. 16,923. Improvements in camera attachments. Willis Eugene Phillips, Norfolk House, Norfolk Street, Strand, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

SELF-DEVELOPING PLATES.—No. 8,911, 1905. The invention consists of an application to the back of a plate or roll-film of a developer which may be prepared in two parts, kept separate on the plate or film, and which contains borax or boric acid as a constituent. The patentees refer to Backelandt's patent No. 1,201, 1888) and to that of Thornton (No. 17,292, 1899), but their invention is put forward as essentially different from either of these. They prepare a concentrated developing mixture in a thick or semi-fluid condition, and containing, as a preservative and alkaline constituent, borax, boric acid, or a soluble borate, and this mixture we spread on the back of the plate, film, or the like. They allow the developing composition to dry, and if, after such a plate or film has been exposed in the camera, it is immersed in water, the water will dissolve the backing and so become itself a developing fluid. The following mixture for backing is convenient in use:

Metal .....	2 grains.
Hydroquinone .....	5 grains.
Metabisulphite of potassium.....	½-1 grain.
Bromide of potassium .....	½ grain.
Borax .....	10-20 grains.
Gum or other suitable colloid .....	¼ grain.

Water, sufficient to make a thin paste.

These materials are ground together, applied to the back of the plate, and allowed to dry. The quantity stated above is sufficient for a "quarter-plate." When the composition is to be applied to the back of a "roll film," it is necessary to so adjust the constituents as to secure flexibility. The inventors quadruple the above quantities (except the gum) and mix the ingredients with fifty drops of gum arabic mucilage, four drops of glycerine or syrupy glucose, and sufficient water. This quantity of mixture will serve for coating the back of an ordinary "six-exposure" quarter-plate roll film. Instead of

incorporating all the constituents of the mixture, sometimes keep separate the reducing and alkaline constituents, and spread these on adjacent areas on the back of the plate, film, or the like. Composition as given above may be divided into two or more constituents as follows: The two grains metol and the five grains hydroquinone and the metabisulphite of potassium may be mixed with a little gum, and spread on a portion of the plate. The borax, or accelerator, similarly treated at another, and the bromide, naturally occupying less space, may be placed apart, from whence it can be removed by scraping or sponging before development, should this course be deemed desirable. Similarly, the other constituents may be adjusted or proportioned by the operator. A thin coating or wash of gum arabic or sugar in solution, or a mixture of both, is a protection which is applied over the developing composition when exposure to trying atmospheric conditions is anticipated. In order to avoid excessive reflection of light from the back through the plate in the case of the single composition, and an unequal reflection in the case of the developer in separate constituents, a "light absorptive" layer is placed between the support and the developing materials; but in certain cases the "light absorption" layer may be between the sensitive film and the support, but the inventors make no claim to the combination of sensitive film, absorptive layer, and support, as same forms the subject of Oakley's patent, No. 2,986, of 1895. In the former case the "light-absorptive" material may be either a transparent colour, a sheet of opaque substance or a pigment, in the second case a dye or stain that will wash out during development and fixation. As an example of the light-absorptive medium which is interposed between the sensitive stratum and the support, the following is given:—

Gelatine, 1oz.

Water, 16oz.

Dissolve by heat and add:—

Crocein scarlet, 3.B. 5 grains.

The solution is applied to the support and dried before coating with sensitive emulsion. Sometimes collodion or the like is used as a vehicle for the colour. For coating the back of the plate a similar composition is used, or, in place of the crocein scarlet or other dye, lampblack or other suitable pigment. When our developing composition forms one unbroken covering over the back of the plate or film, it is convenient to incorporate the "light-absorptive" material with the developing constituents; in this case 1-10 grain crocein or lampblack or other suitable dye or pigment is added to the developing mixture described above. In order to carry out the invention as applied to "roll film" with certainty of success under all climatic conditions, it is necessary to interpose an impervious medium between the convolutions of the film, otherwise the developing composition might act on the sensitive stratum. The black "needle paper" ordinarily used to protect "roll film" from light is seldom or never sufficiently impervious to chemical action, but is rendered sufficiently impervious by drawing it through a celluloid varnish or the like. William Fraser Cloughton Kelly, 22, Winchendon Road, Fulham, London, S.W., and John Arthur Bentham, 51, Claverton Street, London.

**FLASHLIGHT.**—No. 22,294, 1905. The invention is a box for the combustion of magnesium powder, provided with valves for the escape of the fumes to the outer air. Letter *a* indicates the box in which the combustion takes place, such box being closed in front, and capable of being raised or lowered as usual in slides in the upright, *b*, such movement being facilitated by the employment of a counterweight, *c*, connected to the box, *a*, by the cord, *d*, passing over pulleys, *e*. In the box, *a*, and preferably at the top thereof, may be a slot or slots provided with flaps or valves, *r*, normally closed by counterweights, *s*, or other suitable means, and capable of opening inwardly under atmospheric pressure upon the production of a partial vacuum within the box. The pump for producing such vacuum may be of any suitable construction, and may consist, for example, of a box, *f*, having a portion of its sides collapsible, as shown at *g*, the said box, *f*, being provided with

a suitable outlet valve at *h* and inlet valve at *i*, the outlet being connected by flexible or other pipes or tubes to a ventilating shaft or chimney. This box, *f*, may be either attached to the stand, *j*, of the instrument, or may be placed in any other convenient position, and may be operated by the hand or foot of the attendant; in the drawing a handle, *k*, is shown for raising and lowering the lid, *l*, so as to expand or contract the collapsible sides, *g*. If not secured to the stand, *j*, the box or pump, *f*, may be connected to the box, *a*, by means of a flexible pipe or tube, *m*. The said pipe, *m*, is preferably capable of being readily connected to and disconnected from an expansion box, *n*, which may be placed at the lower end of a pipe, *p*, depending from the bottom of the box, *a*, and which expansion box may be provided with an outlet valve, *t*, controlled by a light spring, *v*, permitting a slight escape of

air from the said box into the room when the pressure within the apparatus is momentarily increased by the combustion. The action of the apparatus is as follows: After the fumes have been produced in the box, *a*, the operator lifts the handle, *k*, thus closing the valve at *h*, opening the valve at *i*, and drawing the fumes into the box, *f*, through the pipe, *p*, expansion box, *n*, and flexible pipe, *m*; atmospheric air then flows into the box, *a*, through the aforesaid valves, *r*, in the roof, or other part of the said box, *a*, replacing the gases withdrawn by the pump. On the lowering of the handle, *k*, the valve at *i* closes and the gases drawn into the box, *f*, are expelled through the valve at *h*. The number of strokes of the pump necessary depends upon its size and the volume of gases produced. If the pipe, *m*, be disconnected, the box, *a*, can still be used in the manner usual in flashlight photography without conveying away the fumes. Harry Kirby, 21, John William Street, Huddersfield.

**FOLDING CAMERAS.**—No. 14,954, 1905. The invention which requires the figures for its detailed explanation, comprises: (1) a holder or "adapter" at the rear of the camera of any suitable type or character—for example, after the manner of the "adapters" at present in use for containing a film pack or flat package consisting of a series of separate flat films provided with film operating tabs, which latter extend to the exterior of the holder or adapter so as to enable same to be moved by the operator; (2) a bellows, one end of which is attached permanently to the front—i.e., the side towards the lens—of holder or adapter, and the other end of the bellows attached to a lens-carrying front; (3) a lens-carrying front attached to the bellows, provided with a detachable lens and shutter, the lens and shutter being readily detachable or otherwise as desired, and also this lens-carrying front may also be provided with a special revolving carrier or turn-table arrangement for the lens

so as to enable the lens to be de-centred; (4) means (adapted to be extended or collapsed, connecting the holder or adapter to the lens-carrying front of such a character as will limit the distance which the lens-carrying front can move from the holder or adapter, and will hold these parts rigidly in position with respect to one another when the camera or apparatus is extended ready for use, and which, on the other hand, will enable the lens-carrying front and the holder or adapter to be laid flat together close to one another in a very compact form, and which means will themselves occupy a very small space when folded or collapsed. James Alfred Sinclair, 54, Haymarket, London.

## New Apparatus, &c.

"The Kino." Sold by Chas. Zimmermann and Co., 9, St. Mary-at-Hill, London, E.C.

This is a very ingeniously constructed cinematograph of such a size that it can be conveniently carried in a case measuring only 3in. by 6in. by 6in., yet its clear, sharp pictures—1cm. by 2cm. in size—proclaim it as far from a toy apparatus. The whole of the mechanism is enclosed in the camera, which is fitted with a lens working at  $f/2$ , though for taking the negatives it is, of course, advisable to use  $f/4$  as the largest aperture. The film, which can be obtained in various lengths up to 15m., is filled in the dark slide on a reel, thence brought into the camera, passed down the focal plane, and clamped on to a lower reel which is fitted with a clockwork arrangement, which automatically reels up the exposed film as it is passed through the camera by the action of turning a handle. This handle actuates the shutter, which consists of two fans, adjustable to any width so that it acts in the same way as a focal-plane shutter.

For development the film is wound on to a flat frame, which will lie in any 12in. by 10in. dish, so that there is no difficulty in developing, fixing, etc. To make the positive, the negative and a positive film are passed together through the camera, the lens being directed to any source of light.

The camera itself is used as the projecting instrument, the full aperture of the lens now being used. Any ordinary lantern can be used, or a special lantern is supplied if desired. The size of the disc obtained varies naturally with the illuminant: with the limelight it can be 6ft. by 4ft., with acetylene 5ft. by 3ft., or with an ordinary incandescent gas burner 3ft. by 2ft. The results are excellent, and there is no flicker practically.

The whole outfit is well made, neat, and places within the reach of everyone, at an extremely moderate price, an efficient cinematograph which may be a source of endless amusement at winter parties.

A Combined Measure, Bottle, and Funnel. Sold by W. Butcher and Sons, Farringdon Avenue, London, E.C.

An addition to the many useful dark-room accessories which have emanated from this firm has been made by Messrs. Butcher in the shape of this piece of apparatus, the purpose and advantages of which are almost sufficiently explained in the drawing. The bottle

effectually avoids the difficulty experienced by some of pouring small quantities of liquid from an ordinary bottle, and the double graduation of the bottle adds to its usefulness when compounding a developer by diluting a strong stock solution. The bottle is made in two sizes, 10 and 20 oz., at 1s. and 1s. 3d. respectively.

## New Materials.

The Defender Papers. Sold by A. E. Staley and Co., 19, Thavie Inn, E.C.

Some samples of these new papers have been proved by us the last week with good results. The first we tried—a glossy print-out paper called "Disco"—was found to print quickly with a long and somewhat soft scale of gradation. It tones readily both in the separate and combined baths to satisfactory colours.

"Argo" is the name of a developing paper for gaslight work which is issued with various surfaces, and also on tinted paper. It is made also in three different varieties of emulsion: "Carbo Argo," for contrasting effects or soft negatives, "Portrait Argo" for soft effects and contrasting negatives, and "Special Portrait Argo" for very hard negatives. This large choice between twenty different varieties of surface and three different emulsions will enable any worker to obtain any desired result from his negatives, no matter of what character they may be.

The blacks obtained on this paper are excellent in colour and rich in depth, and perfectly pure whites are obtainable. The developer we used was not that advised, but one with which we are familiar and obtained satisfactory results.

We also note that ten varieties of "Monox," a new bromide paper by the same makers, is to be issued, for although arrangements have been made for the supply of these papers to the English market we understand that they are not yet obtainable.

"PUNCH" on amateur photography:—"A Member of Parliament suggested last week that a representation should be made to the Natal military authorities in favour of substituting photography for decapitation. Those, however, who have suffered at the hands of amateur photographers oppose this idea on humanitarian grounds.

At the Liverpool Association.—To-morrow (Saturday) an exhibition of the work of four members of the L.A.P.A., opens at the association's rooms, Eperle Street, and may be visited free of charge until August 25. The four exhibitors are J. H. Canevali, Dr. John W. Ellis, J. Dudley Johnstone, and John Smith.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
1.....	Hull Photographic Society .....	Outing to Lincoln.
1.....	Hackney Photographic Society .....	Outing to the Zoo.
1.....	Manchester Amat. Photo. Soc. ....	Outing to Middlewood.

3.....	Bowes Pk. and Dis. Ph. Soc. ....	“The Theory and Practice of Self-Toning Papers.” J. J. Griffin & Sons.
3.....	Bradford Photographic Soc. ....	Outing to Hurst Wood.
3.....	Southampton Camera Club .....	Print Competition.
4.....	Hackney Photographic Society .....	Question Box.
5.....	Leeds Camera Club.....	“Metric Weights and Measures.” A. H. Rutherford.
5.....	Worthing Camera Club.....	Outing to Angmering and Decoy Ponds.
5.....	North Middlesex Photo. Soc. ....	Discussion on Enlargements v. Direct Prints.

## Dews and Notes.

**A Word of Thanks.**—Mr. A. W. Brooks, advertisement manager of the *BRITISH JOURNAL OF PHOTOGRAPHY* and the *B. J. ALMANAC*, asks us to express his sincere thanks to the many members of the photographic trade who have evinced a personal interest in his unavoidable absence from business, or have congratulated him on the success of an operation which he has undergone. We are glad to think that others besides ourselves are happy to hear of Mr. Brooks's complete recovery.

**The Northern Exhibition, 1907.**—The preliminary prospectus and entry form of the Northern Photographic Exhibition has just been issued, and is obtainable from the honorary secretary, Mr. C. F. Inston, 25, South John Street, Liverpool. The Walker Art Gallery has been again placed at the disposal of the management, which will continue the exhibition from March 22 to April 13 next year. With a committee, presided over by Dr. Thurstan Holland, and served by a secretary of the vigour and experience of Mr. Inston, there ought to be no doubt of the next year's northern show accomplishing the Herculean task of outdistancing its predecessors. We wish Liverpool all success in 1907. The photographic trade should note that opportunity will be given for it to be represented.

**ECHOES of the Southampton Convention** are awakened by the current issue of our Dutch contemporary, “*Lux*,” edited by Herr J. R. A. Schouten, who contributes to this journal, “*Eenige indrukken van het 21e congres der ‘Photographic Convention of the U. K.’ gehouden te Southampton.*”

**CHANGE of Address.**—Mr. G. F. Perrins, the Hon. Secretary of the West London Photographic Society, has removed from 20, Rockley Road, W., to 2, Amhurst Avenue, Ealing, W., where all correspondence or inquiries should be addressed.

In his Presidential address to the British Association at York, Professor E. Ray Lankester stated that the invention of the dry plate, which has made it possible to apply photography freely to astronomical work, is the chief cause of the great expansion of astronomy since 1881. It was the dry plate which made long exposures possible, and thus enabled astronomers to obtain regular records of faintly luminous objects, such as nebulae and star-spectra. Roughly speaking, those visible to the naked eye may be stated as eight thousand; this is raised by the use of our best telescopes to a hundred million. But the number which can be photographed is indefinite, and depends on length of exposure: a thousand million can certainly be so recorded. By the photographic method hundreds of new variable stars and other interesting objects have been discovered. New planets have been detected by the hundred. Up to 1881 two hundred and twenty were known. In 1881 only one was found; namely, Stephania, being No. 220, discovered on May 19. Now a score at least are discovered every year. More than five hundred are now known. One of these—Eros (No. 433)—is particularly interest-

ing, since it is nearer to the sun than is Mars, and gives a splendid opportunity for fixing with increased accuracy the sun's distance from the earth. Two new satellites to Saturn and two to Jupiter have been discovered by photography (besides one to Jupiter in 1892 by the visual telescope of the Lick Observatory). One of the new satellites of Saturn go round that planet the wrong way, thus calling for a fundamental revision of our ideas of the origin of the solar system. The introduction of photography has made an immense difference in spectroscopic work. The spectra of the stars have been readily mapped out and classified, and now the motions in the line of sight of faint stars can be determined. This “motion in the line of sight,” which was discernible but scarcely measurable with accuracy before, now provides one of the most refined methods in astronomy for ascertaining the dimensions and motions of the universe. It gives us velocities in miles per second instead of in an angular unit to be interpreted by a very imperfect knowledge of the star's distance. The method was in 1881 a mere curiosity, which Huggins was almost alone in having examined, though visual measures had been begun at Greenwich in 1875, and were continued for many years, only to be ultimately found to be affected by systematic error. The photographic method started by Vogel in 1887 really has made all the difference, and this work is now a vast department of astronomical industry. Among other by-products of the method are the “spectroscopic doubles,” stars which we know to be double, and of which we can determine the period of revolution, though we cannot separate them visually by the greatest telescope. Work on the sun has been entirely revolutionised by the use of photography. The last decade has seen the invention of the spectroheliograph—which simply means that astronomers can now study in detail portions of the sun of which they could previously only get a bare indication.

“**Houghtons' Quarterly**” is the title of a new quarterly issued by Houghtons', Limited, intended for amateur photographers. Its aim will be to describe and picture the latest novelties in photographic apparatus and materials, and it will be sent free to all applicants.

## Commercial & Legal Intelligence.

**FAILURE of an Enlargement Business.**—The first meeting of the creditors interested under the failure of Alfred Margand, photographic enlarger, carrying on business at 115, Seven Sisters Road, N., took place on Tuesday, August 7, at the London Bankruptcy Court, under the presidency of Mr. G. W. Williams, assistant official receiver. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £674 3s. 4d., of which £631 10s. was due to unsecured creditors; to fully secured creditors £35, the value of the securities being estimated at the same amount. The total liabilities expected to rank against the estate for dividend were returned at £637 3s. 4d., and the assets consisted of stock in trade valued at £2. The net assets, after deducting the claims of preferential creditors, were returned at nil, thus leaving a deficiency of £637 3s. 4d. It appeared that the debtor originally started in business as The Columbia Guitar and Zither Company, at New Oxford Street, W., and he also gave lessons on the zither. For some time the business was successful, but having prosecuted two of his travellers for alleged embezzlement, he abandoned the proceedings afterwards, with the result that the travellers sued him for malicious prosecution, and judgment was obtained against him for £200, and the costs of the proceedings also went against him, with the result that he now owed about £500 on that account. He tried to make an arrangement to pay the damages and costs by instalments, but his offer was refused. In consequence of these proceedings he went to Aberdeen in 1903, and started in business there as a photo enlarger, and subsequently he returned to London and carried on the same kind of business at his present address. He had no offer of composition to submit to the meeting. The chairman said that as that was the case, there being a summary order, the case would have to go into bankruptcy. Mr. Jones, who appeared for a creditor, said he understood that the debtor was now carrying on business as the Anglo-French Art Company, in Queen's Road, Bayswater. Debtor, however, stated that he did not know of any such company, and he certainly

had nothing to do with it, even if it existed. Mr. Jones said the name of the person who was supposed to be carrying on the business was a Mr. Zeiflin, whose name cropped up in connection with certain interpleader proceedings, in which debtor was interested. Debtor said he had a Mr. Zeiflin among his creditors, but he was a barrister. He did not think he carried on an art business. Mr. Jones stated that during the interpleader proceedings it came out that the sum of £200 was withdrawn from the bank as soon as the sheriff took possession of the effects at debtor's house, and the explanation then given was that the £200 had been sent to America to be held in safe custody by Mrs. Margand's brother. Debtor alleged that no such question was ever asked him, neither did he give the answer alleged. He did not know whether his wife gave those answers. At all events, she did not give them in his presence. Mr. Jones said the banking account was in the debtor's wife's name, and she drew cheques on the account. There was nothing in the bank at the present time. He suggested that this £200 ought to be traced. He knew of the existence of other assets, which, together with this £200, would be sufficient to pay the creditors 20s. in the £. Debtor said he had disclosed all his assets. Mr. Jones said the whole object of the debtor in filing his petition was to get rid of this judgment which was hanging over his head. He did not, however, file his petition until he had disposed of all his property, but as soon as he had safely disposed of it, as he thought, he seeks the protection of the Court, but he had failed to disclose all his assets. Debtor stated that he had had the bailiffs in the house on nine different occasions, and they sold up everything. They not only sold his own goods, but they also sold the negatives of his customers, which were only held in trust for him. Almost every day he had to go with a solicitor's clerk to the bailiffs, Messrs. Wright and Odell, and tell them that unless they handed over his customers' photographs he should take proceedings against them. Latterly he had had the bailiffs in the house almost every week. He suggested that his two former travellers, who only earned about £1 per week, could not afford to pay all the law costs they had incurred, and that the costs were being found by their solicitors. Mr. Jones objected to such a statement being made. He thought it was a case in which an independent trustee should be appointed, as this was a case that required a very searching investigation, in order that the assets might be traced. The chairman pointed out that a summary order for the administration of the debtor's estate had been made, therefore the creditors would require to pass a special resolution in order to get an independent trustee appointed, and after a long discussion it was decided to leave the matter in the hands of the Official Receiver for summary administration in the usual manner.

#### FORTHCOMING EXHIBITIONS.

August 6: Andover and D. H.S.—Sec., W. I. Gradidge, Jubilee House, Andover.

September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.

Rotherham Photographic Society.—Annual exhibition. "Open." October 17 to 20. Entries close October 8; exhibits, October 13.

November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismire," Stafford Road, Southsea.

November 20 to Sefton Park Photographic Society.—Sec., A. W. Parr, 34, Loudon Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.

December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

1907.

February: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

## Correspondence.

- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### A COPYRIGHT QUERY.

To the Editors.

Gentlemen,—Notwithstanding the many answers you have already given to inquiries as to the law of copyright in relation to photography, may I venture to suggest that many amateurs are still in uncertainty on a point that constantly crops up. A has his photograph taken in the ordinary way of business by the firm of B and C, pays for his prints and gives no undertaking, written or implied, that he will assign the copyright to B and C. But when he receives his prints he finds on each the word "Copyright Registered". It is safe to assume in such a case that A knows nothing of the copyrighting of his own portrait, and the question arises whether, if B and C have copyrighted A's portrait without his knowledge and consent such action is not "ultra vires," and whether it would protect, as it is doubtless intended to do, B and C from A having copies and possible enlargements made from the print with which they had supplied him.—Yours truly,

WALTER S. CORDER.

North Shields. August 6, 1906.

[The Copyright Act is quite clear on the point raised by our correspondent, in that it expressly withholds the copyright from the photographer, who receives "valuable consideration" for his work unless there be an assignment in writing to him. The marking of the prints "Copyright," when they are not the photographer's copyright, is an illegal act, but though we know of no case in which it has been visited with a penalty it certainly does not deprive the customer of his rights.—Eps. B.J.P.]

### A NOTE ON THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—It appears that Mr. Payne does not yet understand that when the values of  $K$  and  $\gamma$  are found the actual times of development may be calculated at once. At the same time I agree with Mr. Payne that it is better to give the actual times of development necessary than to expect the user to work them out; and, personally, I always follow this course. Whether  $K$  and  $\gamma$  are commonly used in actual practical plate-testing appears to depend upon how far mathematics and complicated instruments like a developing thermostat are utilised in this work. If these requisites are to hand it is quicker to find  $K$  and  $\gamma$  and from these calculate the times of development, than to work in any other manner.—Yours truly,

Croydon,

August 3, 1906.

C. E. KENNETH MEES.

To the Editors.

Gentlemen,—I am sorry I was unable to answer Mr. Payne's further letter on "Sensitometry" before, but Mr. Ferguson's exposé of the question should enable anyone to grasp the quite distinctive and particular meanings and values of the two constants,  $K$  and  $\gamma$ . Briefly,  $\gamma$  is the density or contrast giving capacity of the plate;  $K$  the rate at which that density or contrast is developed. The actual  $\gamma$  reached depends on both, but as an example of their separate nature, one may note that  $\gamma$  is independent in general of the developing temperature, etc., while  $K$  is directly influenced by these, and in manner quantitatively measurable. Mr. Payne further states that for the figures he gave in his first letter,  $K$  and hence  $\gamma$  are obviously wrong. This I fail to understand entirely, and must again point to the correspondence between calculated and graphically obtained values of  $t\gamma$  obtained from Mr. Payne's figures. Where  $K$  and  $\gamma$  are obtained from only two readings by the tabular method, the graphic method gives a useful check, but does not supply all the information possible. The correspondence for  $t\gamma$  is the method

checking, of course, as employed in my first letter. With thanks to Mr. Ferguson and Mr. Payne.—I am, yours truly, S. E. SHEPPARD.  
Aldeburgh, August 3, 1906.

### ON PACKING NEGATIVES FOR POST.

To the Editors.

Gentlemen,—To professional photographers the old-fashioned method of packing negatives for sending by post has several disadvantages. It is untidy, especially when shavings are used, and the wooden boxes and lids soon get split up after a few journeys. Sometimes the gum label will not stick to the rough wood, and a stray nail will occasionally damage the negative. Amateurs frequently

have occasion to send a negative by post, and who has not read in "Answers to Correspondents," "It is impossible to advise as your negative arrived in a thousand pieces"? The writer, who has had a great deal of experience in packing negatives, has at last hit upon the following plan, which is economical in every way, of time when packing and unpacking, and—of negatives.

Required: An empty plate box and six pieces of corrugated paper, of the same size as the negative to be packed, two pieces of stout

cardboard twice the size, string and label. The lid of the plate box is glued to the centre of one piece of cardboard and marked "Lid," the bottom being fixed to the other piece in the same manner. Four slits are now made in each piece of cardboard at the centre of each side from the edge to the box, and "V" cuts made to allow the string to slip into the slits easily. This completes the "packer," and a boy can make a lot of them in an hour. The box is used as follows: Place three pieces of corrugated paper in the bottom half, then the negative in its envelope, marked with instructions and name and address of the sender, next three more pieces of the corrugated paper, put on the lid and tie tightly with string, which should be passed through the slits. The negative is now surrounded with four cushions packed with air, and is quite safe. The package is undone by just cutting the string. It is light, and can be used over

and over again. Should it be required to send larger sizes than whole-plate or several negatives in one packet it is only necessary to increase the thickness of the cardboard, or to use thin wood, as sold for backing up picture frames. Several negatives packed tightly together with nothing but flat sheets of paper between go safer than when separated. Finally, it should be noted that stamps should be affixed to a separate "tie-on" label rather than to the box, and the address should be written on both. Also, that the post office will stick a red "Fragile" label on a parcel if requested to do so. The photographs of the arrangement in pieces and packed for postage will explain any points which the writer has not made quite clear.—Yours very truly,  
D. B.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I am very interested in this correspondence, though I am just now neither an assistant nor an employer, but am trying to work up a business for myself. A correspondent, a few weeks ago, quoted: "Out of the fulness of the heart the mouth speaketh." I am using the quotation in a rather different sense, and am writing from the very fulness of my heart, as I have had experience of employers and others, which, I believe and hope, is unique. There is often in letters on this subject something to the effect that one who gets a small salary is not worth more, but this is not always a fact. I received a training from a firm of Royal Photographers, and some time after leaving them I had to give up a place on account of bad trade. Now comes an answer to the last line in "C. H. B.'s" letter in the current issue. I had good references, and could write a good letter, and answered every possible advertisement, but was months before I obtained a situation as outdoor operator at 25s. a week. After I had travelled over 150 miles, I found my employer was a common tout, with whom I had to travel round and photograph public houses and "building groups," etc. My dark room was a cupboard where I could not stand upright. There were many more uncomfortable details, but this is only the first man I would like to write about. It was a nice time for a youth of education and brought up among refined people. After a month of this the man suddenly refused to pay my wages, and showed himself a bully. As I had a chance of a place in another town I could not stop to go to law, but found the new place scarcely better. I had a certain amount of pride, and having elected to keep myself, I did not care to write home and acknowledge myself beaten, even if I had had the railway fare. I then passed through a hard winter, and was glad to take any job to keep me alive. Those young men with plenty of money may talk about "seeking another situation," but it is very difficult when one cannot wait long. I am not ashamed to say that I worked for a "backyard" man at 18s. a week for several months to tide me over the winter. In every other respect but the wages he was a fair and considerate employer in comparison with most. The next man I would like to tell about had a nice little business, and turned out good work, but he would not pay more than 20s. a week for a printer and outdoor operator. I told him I could retouch fairly, but without seeing what I could do he laughed at the idea of a young man retoucher. Before accepting me (at £1 a week) he insisted on a reference from a member of the P.P.A., and with some difficulty I got a gentleman with whom I had only very slight business acquaintance, to give me one, and after a few questions he was kind enough to write evidence of my respectability, etc. I remember that man with feelings of gratitude, but, alas, my new employer made me develop three half-plates in a very uneven 12 x 10 dish, with not more than 30ss. of developer. I was using 60ss., and he was afraid the extravagance would ruin him. The negatives were all over-exposed, and every other head had one shoulder cut off, yet I was expected to produce as good a vignette from these as from a properly exposed and centred head. "I went away from there," as Mark Twain would say, after the first week. A few months after the proprietor sold the business, and his name was not to be found on the P.P.A. list. I have met with only one employer who really encouraged me to improve myself. He would discuss any technical point, and we would try all sorts of new ideas. I really improved while with him, but unfortunately he could not pay me as much as I thought I was worth, and I took an offer from another firm. I am giving these examples as an offset to the letter of "A Disgusted Employer," who, perhaps,

has had the same experience with assistants as I have with employers. I was once "sacked" after a fortnight for an obviously trumped-up reason, and was privately told that "the boss never kept on anyone who wouldn't carry on dirty conversation"! On one occasion, when seeking work (many assistants have to tramp in search of employment like labourers), I was told by a man whose business had been a well-known one, that he would employ me as an apprentice or improver without salary, and that he got all his work done that way. Another time I cycled 12 miles to see a man whom I had previously written making the appointment. On arrival he sent word to say he was too busy, and it was no good waiting, I must write him, which I did; and, getting back, scribbled in pen on a torn scrap of paper:—"Dear Sir,—You would not suit me." I had found out in the meantime that I should have had to work from 8 a.m. till 9 p.m. every day, and on Sundays and Bank Holidays, etc., so that the only holiday in the year would be Christmas; and all this for £1 per week, and to operate, retouch, prints, etc. This was a flourishing business. Another man engaged me, after some haggling, at 22s. 6d., to rise to 25s. after a month's trial. I was to assist in studio, outdoor, operate, retouch, work in B. and W., print in P.O.P. and bromide, enlarge, develop, etc. The work of the studio was really very nice, and it had a well-to-do clientèle. On the Saturday I was paid 22s., and on mentioning politely the extra 6d., was told that "I never split shillings." The second week I was informed that in addition to the other capabilities mentioned I ought to print in aristo, platinotype, velox, and two varieties of self-toning paper, and get the same results as the boss. Print bromides in the dark room, and pop out every few minutes to see how the frames were getting on, with half-a-dozen kinds of paper in them. I could not do that, so I preferred to go. I spent one winter in a cold district in a room with stone floor, stone walls, and a glass door that let the north wind in all round, from 8 a.m. to 7 p.m., six days a week, without any heating. As there was only about three hours work a day I had to idle the rest of the time away, and was not allowed to read. I was entrusted with the entire business, taking all money and ordering stock, etc., as the boss was ill for weeks at a stretch several times. I was thus exposed to every possible temptation to revenge myself for the privation endured on account of the long cold days and a low wage, and yet was afterwards coolly told that I had only done what I was paid to do, and no thanks were required. I am sure if employers would consider the comfort of their hands the latter would respond by trying their best for their employers, at least those with a trace of the right spirit in them. On the other hand, "A Disgusted Employer" is right in using "drastic remedies," but, at the same time, if he watches for any improvement in the way of a little act of extra care, let him encourage by words and actions the smallest signs, and I am sure he will be repaid over and over again.—For obvious reasons I sign myself

HARD DONE BY.

To the Editors.

Gentlemen,—I have been reading with great interest the last few weeks the letters from "Disgusted Assistants." Now we hear from a "Disgusted Employer," which is more interesting to me, as it gives me a new view of things. Not having changed my situations so frequently as most assistants I am not in the position to criticise employers. Now having read "Disgusted Employer's" letter, I am hardly surprised at him having trouble. I think if he paid proper assistants and not incapable females (which he undoubtedly has according to his own showing) his troubles would be considerably lessened, if not entirely ended.

Then he says the professional amateur does far better work than the assistant professional, who is a mere and most ignorant dabbler. Why, he has evidently never had a good assistant. Perhaps he is like many others who employ girls, and expect them to do men's work, rather than pay a good man a fair wage, which would be cheaper to him in the end, considering the material they waste for him. I also think that all who understand the difficulties surrounding the production of good enlargements will agree with me in saying that the man who entrusts this work to a female is certainly looking for trouble, and I can see it sticking out like the handle of a coffee pot; and I question whether such a man would know the difference between good enlargements and bad ones.

Another point which I think is the cause of a lot of trouble is what has happened in my own town, and I think must be universal. A

distinctly third-rate professional advertises for a first-class operator and retoucher. Now, what he really wants is a third-rate operator who will not object to muck around generally. The result is he gets applications from first-class assistants, and perhaps engages one. When he arrives he is naturally annoyed to find he has come perhaps on a long journey to get disappointed. Then the employer gets a bit of a name; the other assistants hear what has happened, and conclude that they have just as much right to answer a first-rate advertisement as their employer has to advertise for a first-class hand. This means that should they become engaged (perhaps on another man's speculations) they are not able to keep the new situation; hence the phrase we often see: "Duffers please not apply." In the first case, assistants become "disgusted," in the latter employers get likewise, and until we all understand what first-class really means there will always be this trouble. What one man will call high-class another will call utter rubbish.

BONA FIDE.

To the Editors.

Gentlemen,—As one of the early members of the P.P.A., I welcome the letters of "Disgusted Assistant" (whom I will call "D.A." for short), and, although his criticism is sometimes a little wide of the mark, it is a good deal better than the too prevalent apathy.

The points raised by the correspondence are:—

1. Status of Members of the P.P.A.
2. Examinations for P.P.'s
3. Competency of employers to recommend assistants for certificates.
4. Examination as a condition for granting certificates.
5. Hours and remuneration of assistants.
6. Assistants' Trade Union.

No. 1. "Othello" and "Another D.A." have pretty well disposed of this point. It is evident that, founded as the P.P.A. was as a sort of Trade Protection Association, it was bound to admit as P.P.'s who cared to join, but the men who have the welfare of the association and of photography as a calling most at heart, and who form the driving power of the movement, as far as I can judge from attending the meetings, are men who can do good work themselves and are doing their best to stimulate a high standard of efficiency on the part of assistants.

They feel that, so far as operators at any rate are concerned, the P.P.'s of the future will be drawn from the assistants of to-day, and therefore, that to grow a race of efficient assistants is the best way to raise the standard of professional photography of the future.

No. 2. Tests for employers as members of P.P.A. This is not practicable at the present time.

No. 3. The committee safeguard themselves somewhat by reserving the right to see bona fide specimens of the candidates' work, if required. This is, perhaps, not sufficiently understood, but no doubt practical examination is the best test.

No. 4. I have felt from the first that holding examinations is the only way to get assistants to take up certificates. If anyone is going to pay a fee he wants something more for his money than a testimonial, and an employer seeking help would attach more importance to a certificate awarded after impartial practical test than to a testimonial which may be given by another employer whose standard may differ from his own.

The difficulty in the way is that of expense, and it would mean having to incur the expense whether few or many candidates entered for the exam.

Nos. 5 and 6. "D.A." will be glad to know that at a meeting of the P.P.A. not long ago the question was raised as to a guarantee of efficiency on the part of an assistant carrying with it a recognition of the P.P.A. that the holder was entitled to a definite standard of remuneration—i.e., that the holder of a certificate should not be expected to take less than a certain salary.

To ensure this assistants will have to combine and form an organisation of their own, which might very well co-operate with the P.P.A., although it must not be supposed that there would never be any divergence of opinion between them—for the interests of employers and assistants can never be exactly identical.

The hours and remuneration are matters that need consideration, and an association of assistants would be the most suitable body to take account of them, the chief difficulties in the way of such an

sociation being started being the lack of opportunities for meeting together, the many grades into which employees are divided, the indifference of assistants themselves. It must be borne in mind that unskilled labour, whether on the part of an individual in business for himself, or of an employee, will command but a poor price. The public will not pay much for what it can do for itself equally well, and when every errand boy can produce a photograph of some sort without difficulty. Something of good quality will have to be turned out if a living remuneration is to be obtained.—Yours faithfully,  
A MEMBER OF THE P.P.A.

August 6, 1906.

#### To the Editors.

Gentlemen,—I have been reading the correspondence in THE BRITISH JOURNAL on the "P.P.A. Certificates to Assistants," but I like the title of "A Disgusted Assistant's" letters ought rather to be "An Unwarranted Attack on 'Professional Amateurs.'" I belong to that class, and might be allowed to say a few words on the subject. I happen to know a good few "Professional Amateurs," some of whom stand at the top of the tree in their profession. Others stand far above their "Trained Professional" brethren in their respective towns, but I don't know one who lives for the title "Backyarder," or "Stickyback" man. On the other hand, I know a good many "Trained Professionals" who do not seem to be able to rise above that cheap and nasty work on glazed P.O.P. to clubs, and who also advertise, as a specialty, I suppose, "midget photos," two positions from 2s. 6d. for photo. on postcards, 3s. 6d. per doz.; Cabinets, 3 for 2s. 6d. It happened to drop on a town with a population of 17,000 in which "Trained Professional" had succeeded in establishing a business. Though a purely working-class population, I at once set my face against cheap or nasty work, also midgets or stickybacks, and after twelve years my turnover amounts to more than double what it was three years ago. My prices are much higher than when I started, and I use for general work C.C. matt platinum and paper, also carbons, on the highest-class mounts, sometimes using stock mounts altered at an extra charge to suit my taste. There are nine "Trained Professionals" within three miles from my studio, and I would not exchange businesses with any of them except one.

Referring to "Assistants' Certificates," my opinion is that they are of value for little less than the cost of the paper on which they are written.

The British people are so fond of being gulled, and certificates in employers are generally written with something like that effect in view. Certificates by examination are frauds; generally forward and cheeky get through, where a really clever person is often through backwardness or sensitiveness. Two of my pupils who have just finished their education at the Academy have always held their own at the top of their classes, and in exams. they always come out a good way down the list. Now just one word or two on the P.P.A. I understood when it was started that it was meant for the betterment of photography in general, to put down price-cutting, photographic frauds, etc., and to gain that end all the "backyarders" and "stickyback" men, including the "three cabinets for half-a-crown" men, must be got rid of and taught to pursue a higher ideal than the degrading work they are doing.

If you debar this class of membership, then you defeat the object of the P.P.A., just like the Temperance party in this town who run Saturday evening concerts during the winter season as a winter attraction to the public houses, but at the same time advertise So and So's whisky in the most prominent part of their programmes. No, gentlemen; if the P.P.A. is to be made a select body with no other object than granting the use of the letters P.P.A. as a sort of degree to a few who are so very ambitious, then I withdraw my subscription at once.

The P.P.A. might do worse than ask all who send in pictures to their proposed exhibition to write on back of picture whether "Trained Professional" or "Professional Amateur." Apologising for trespassing so far on your valuable columns, yours, etc.,

PROFESSIONAL AMATEUR.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- William Charles Hurdle, Prospect Cottage, High Street, Freshwater, Isle of Wight. Photograph of Mr. and Mrs. William Charles Hurdle and Child.  
Frederick Henry Robinson, 5 and 6, St. Pancras, Chichester. Photograph of Group of the Chichester Parcel Carriers.  
Matthew Kirk Dunn, 3, Dixon Terrace, Darlington, Co. Durham. Photograph of Richmond, Yorkshire, Catholic Church Interior.

G. L. Frustrum, York House, Port Erin, Isle-of-Man. Photograph of gulls, Port Erin.

W. C. WILLS.—You will have to prove first from your books that the parcel was sent as alleged, and secondly, that the contents were securely packed. When you have done this the Post Office, you will find, will entertain your claim.

CHARLES H. PRICE.—W. M. Still and Co., 24, Charles Street, Hatton Garden, London, E.C.

LINE DRAWINGS.—1. You gave some time back a special formula with hydroquinone for the development of negatives of line drawings. Although I made a note of it at the time I cannot find it. Will you kindly repeat? 2. Is it possible to use ordinary process or ortho process plates for line work?—LINKSMAN.

1. There are two formulæ which have always given good results in our hands, either of which may be used for all process plates:—

Hydroquinone .....	8 grains.
Sodium sulphite .....	80 grains.
Formaline .....	10 minims.
Water .....	1 ounce.

or

A. Hydroquinone .....	12 grains.
Potassium metabisulphite.....	12 grains.
Potassium bromide.....	12 grains.
Water .....	1 ounce.
B. Caustic potash.....	24 grains.
Water .....	1 ounce.

For use mix in equal parts. 2. As regards the use of ortho process plates, these have, of course, considerable advantage if there is the slightest trace of yellowness in the paper. Provided it is merely a question of black and white there is not much to choose.

COPYRIGHT.—Having obtained special permission to photograph an old fresco in a local building, can I by copyrighting it prevent others from doing the same?—G. L. M.

The query is not quite so clear as it might be. By copyrighting your picture you can prevent anyone from pirating that, but this will not prevent anyone who may also receive special permission from photographing the fresco and selling prints. The Copyright Act, which, by the bye, appears in the "Almanac" for 1906, with some very useful comments, says: "Nothing shall prejudice the right of any person . . . to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene or object."

TEST FOR HYPO.—What is a simple reliable test for hypo in the wash-

ing water of prints? I want one that can be done quickly.—**PRINTER.**

When you think the prints have been sufficiently washed, let them soak for a few minutes in a perfectly clean dish. Then having procured two test tubes of exactly the same bore, place sufficient of the plain tap water in one to the depth of about an inch, and an equal quantity of the water that the prints have been soaked in in the other. To each add a few drops of 10 per cent. solution of nitrate of silver, and warm the print washing water. If there is any yellow colouration, hypo is present. This can be easiest seen by looking down or through the tubes at a sheet of white paper.

**COMBINED BATH.**—Is it possible to use a combined toning and fixing bath with any reasonable hope of permanency of the prints? If so, can you give a formula and method of working?—**AMATEUR PRINTER.**

The fault does not lie so much in the bath as in the method of using it. The following formula works well; does not reduce the prints much, provided that they are treated as described.

Hypo .....	4 ounces.
Lead acetate.....	192 grains.
Salt .....	192 grains.
Precipitated chalk.....	96 grains.
Chloride of gold.....	4 grains.
Distilled water to.....	20 ounces.

Dissolve in the above order and shake well, and allow the bath to stand in the dark till clear. Immerse the prints first in a 10 per cent. solution of salt, rendered distinctly alkaline with carbonate of soda. The above quantity is sufficient to tone about 800 square inches of prints. Use for this quantity and not again. The prints should take at least fifteen minutes to reach the desired tone; if they tone quicker dilute the bath; but use the same quantity of stock for the same area of paper.

**RETOUCHING BROMIDES.**—What are the materials used in spotting and retouching bromide enlargements, and whence can they be obtained?—**ENLARGER.**

The usual medium is conté crayon, which may be obtained in various degrees of hardness from Messrs. Reeves, of Farringdon Avenue, or from any artist's dealer as a rule. Hardmuth's also make special bromide pencils, which can be obtained from any dealer.

**G. L. T.**—We absolutely decline to be drawn into the dispute. It has nothing whatever to do with us, and you must settle between yourselves

**STAND DEVELOPMENT.**—I want to develop my holiday plates by stand development, so as to save a little trouble, if not time. Can you suggest a satisfactory formula, which will act in a reasonable time? I do not want to prolong the operation to hours?—**F. H. GRAY.**

The following has before now done us good service, and the development, except in very extreme cases, is finished in half an hour:—

Ortol .....	10 grains.
Potassium metabisulphite .....	5 grains.
Sodium sulphite .....	65 grains.
Sodium carbonate .....	65 grains.
Water, to .....	20 ounces.

As this quantity will develop a dozen or two of plates in a tank at once, it would probably suit our querist.

**M. J. F.**—As no less than five pages are devoted to the subject in the ALMANAC for 1906, and we had a series of articles on the same subject last year, we think we may justly refer you to these, particularly, as you say that you have both the ALMANAC and last year's volume.

**CAMERA.**—I am about to purchase a 12 x 10 outfit. I may state that I have a studio 22ft. x 14ft. (1) Can I get a camera for indoor and outdoor work? (2) What lenses would be most suitable for taking portraits, groups, etc.?—**FOCUS.**

A heavy pattern of field camera, such as you can obtain from any large houses, will be suitable for both studio and outdoor work. You can have it fitted with a detachable repeating back. You had better consult the advertisement pages in the ALMANAC, from which you can surely suit your requirements. (2) We should advise you to get one of the anastigmat lenses of aperture at least  $f/6$ . Consult the maker's lists.

**LENS QUERY.**—I should esteem it a favour if you would kindly answer me the following question. I am having a studio built, and

length from wall to wall is 25ft. and the width would you please inform me the best lens to take a cabinet full length, up to a 12 group and full length? Would one lens do, or I require two lenses? Any information on the above will oblige.—**STUDIO.**

There is no one lens made that will answer your requirements when used in a studio of 25ft. in length. You will require to do the work. What we would recommend is, for the sizes, a portrait lens, which works at an aperture of  $f/4$  is about eleven or twelve inch focus; and for the larger one of the group type, with an aperture of  $f/6$ , and eighteen or nineteen inches focus. With two such lenses will be able to do anything you are likely to require.

**PROFESSIONAL SINGERS' POSTCARDS.**—In next week's issue I consider it a favour if you will answer or give your opinion the following matter. A party of professional singers called had their photographs taken, for the purpose of having post made. I submitted proof and no fault was found with my but they said they would like to sit over again. This I do to, but instead of coming to me they went to another photographer, had their photographs taken, postcards produced, are now on sale. I was paid nothing for my work, and I be glad to know if it would be contrary to law were I to publish postcards from the photograph I took without their permission.—**N. B.**

If it was understood that you were to be paid nothing by parties, the copyright is yours, and you can publish the cards. But if the parties came to you expecting to pay, and received them on this understanding, all you can do is to tell them for the cost of the sitting. The copyright is theirs; you have no right to use the negative. Look up the article on "Copyright" in last year's ALMANAC.

**WOODEN DISHES.**—I wish to make two wooden dishes, with bottoms, for developing large size enlargements, but I am at a loss to know how to make them watertight. I have seen an employer of mine use a substance something like the appearance of "ark angel" tar, but I cannot say what it was. I presume it would be some sort of varnish; but, as stated, shall be pleased if you will assist me, through your paper, in letting me know how to make dishes watertight.—**STRATHAVEN.**

We cannot, of course, say what the tar-like substance but a good mixture is three parts of plaster of Paris, three of litharge, and one part of resin, made into a paste, with boiled linseed oil and some dryers. To make the wood watertight there is nothing better than: Powdered asphalt, 4 ozs.; micantha, 10 ozs.; masticated rubber, 40 grains. Apply on doors, as the vapour is inflammable; give three coats, allow to dry in between.

**PRINTS IN RELIEF.**—Can you give me any particulars of the process for producing photographs on card in relief, and kindly let me if the process is protected, and who I can apply to for permission to use it?—**G. W. SECRETAN.**

There are a number of patents for the process and other processes which are not patent. (See the ALMANAC, page 845.) In the ALMANAC also for past years you will find descriptions of the patented processes.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

## SUMMARY.

Extracts from Dr. Sedlacek's work on toning bromide prints deal with the copper process, indirect toning methods, and the use of mercury salts. (P. 645.)

The Lumières have patented a new means of filling up the interstices in their colour screens for direct colour photography. The plates, after coating with the coloured starch grains, are subjected to rolling pressure. Developing dishes, flash-lamps, and border negatives are among other patents of the week. (P. 654.)

A paper by Professor Lippmann before the French Academy of Sciences advances a method of direct colour photography which has given results in practice. (P. 644.)

A comparison of ancient and modern vignettes suggest the conclusion that the decadence of the vignette is due to the lack of taste evinced in its preparation of late years. (P. 643.)

Addition of a little chrome alum to the fixing bath in hot weather will forearm the photographer against the dangers of a soft gelatine in the plate. (P. 642.)

A plea for the plain and simple in studio furnishing and decoration is the commendable theme of an American writer. (P. 651.)

Steps are being taken in France towards the exchange of views on methods of photographic survey. (P. 642.)

The British Association at its meeting at York has also manifested an interest in photographic survey and record. (P. 652.)

The death is announced of Colonel J. Gale. (P. 658.)

The first part of a paper by A. Goderus on the principles of stereoscopic photography and vision appears on page 648.

The soundness of business policy of looking after the people who have patronised you, at any rate on one occasion, is the subject of a note on page 652.

## EX CATHEDRA.

### The Photo-graphy of Architecture.

One of our contemporaries has enlivened us during the best part of the holiday season with a discussion on the question of whether it is legitimate to produce architectural photographs that are reversed as regards right and left, and this naturally has led to suggestions (sarcastic and otherwise) with regard to the possibilities of combination printing in architectural work. If such procedure is legitimate with architectural subjects it is quite as much so with paintings, and combination prints made from paintings, showing Turner skies over Leader foregrounds, with a few McWhirter trees judiciously introduced, might be distinctly interesting and just as good advertisements of the profound artistic knowledge of the photographer. We are, however, afraid that this new idea in combination printing will not become popular as regards paintings, for we doubt if any photographer will have the face to attempt such work, however much he may be willing to insult architecture, which is justly called the Mother of all the Arts.

A lamentable feature of the discussion is the obvious fact that those holding such heretical views are interested in architectural photography, and presumably produce architectural photographs. They would probably object to reversed portraits on the ground that the buttons and button-holes appear on the wrong sides, but they are so grossly ignorant of architecture as not to realise the fact that the right and left sides of a church are far more strongly distinguished than the right and left sides of a coat. Further, they do not show the slightest respect for the artist, who probably spent a large portion of his life in designing and arranging the subject, and who gave the most careful consideration to the smallest details. Photographers who hold such ideas as those put forward in the correspondence referred to had much better leave architectural photography severely alone, for it is evident that the art of producing pictures from architectural subjects is altogether beyond their comprehension. The painter who succeeds in such work proceeds on altogether different lines. He realises, as of first importance, the fact that he is in the presence of the work of another artist, and his wish is to discover and paint the particular pictures that the other artist endeavoured to perpetuate in the lasting materials of his craft. In fact the painter if a true artist, prefers to interpret the wishes of the architect and to preserve such effects as may be due to personal influence, rather than make any effort to introduce traces of his own personality. Any attempt to alter or improve on the work of another artist is justly regarded in the art world as intolerable impudence, and the artist is content if he knows that he has honestly and fairly represented the other man's work

under the most favourable conditions. The photographer who attempts to show things as they might appear the other way round, or who grafts out the work of one man selections from that of another, may be a clever photographer, but he is not an artist, and has not the smallest conception of the principles that govern the work of artists.

### A Stereoscopic Myth.

Those who have studied the subject of stereoscopic photography are familiar with the number of devices that have been proposed for the purpose of securing two negative images on one plate in the correct relative positions for printing. For a long time stereoscopic workers have wished to dispense with the operation of cutting and reversing either the negatives, or the positive prints obtained from them, but owing to the neglect of the scientific study of the true principles governing stereoscopy, few, if any, have noted the fact that if by any ingenious combinations of mirrors, etc., two negatives are secured in the proper relative positions, then those negatives are not necessarily the right distance apart to give prints with a proper separation. If this fact were more generally realised it would be readily understood that the advantages of a complex camera giving images that require no reversal, are more or less mythical. Careless workers who care nothing for truth of stereoscopic effect might welcome such cameas as great time-savers, but the net result would be the perpetuation of wrongly-separated positive images, and wrong separations is the fault to which stereoscopic workers are now most prone. The exaggerated and offensively unnatural effects of relief that are so frequently obtained are due entirely to mounting the positives too far apart, though most commonly the defect is attributed to taking the negatives with widely-separated lenses. It is true that with widely-separated lenses the correct mounting of the prints becomes very difficult, if not impossible, but whenever correct mounting is possible, and is carried out, all exaggeration or relief disappears. It may be possible to devise a camera in which the negative images require no reversal and are also the proper distance apart, but it does not appear that the matter of separation is often considered, while it is fairly certain that the usefulness of such a camera would be very limited.

\* \* \*

### A Point in Testing Orthochromatic Plates without a Screen.

We recently had submitted to us a couple of old portrait lenses of the Petzval form. They were called whole-plate lenses, and were, approximately, of the same diameter and focal length. They were apparently copies of the portrait lenses turned out by the house of Voigtlander some forty or more years ago. Both were pronounced good instruments, but one—in spite of their being as nearly as possible identical in diameter and focal length—was very much slower than the other, requiring just about double the exposure. The surfaces of the glasses of both instruments still retained a good polish, and were so far satisfactory. The lens pronounced so much the quicker of the two was examined by taking the glasses out of their cells and placing them on a sheet of white paper. With none of them was its whiteness materially degraded. In the case of the other, however, one lens of the back combination had a decided tint of yellowness that evidently it did not possess when new; but the greatest difference was in the front combination, one of the glasses of which had become yellowed to some extent, and the balsam cementing the

two glasses had acquired a very decided yellow colour. This was quite sufficient to account for the slowness of this instrument, as compared with the other. The point, however, on which we would touch is that, supposing these lenses were to be placed in the hands of two different makers, wherewith to test the orthochromatic quality of a brand of plates without a light filter, the results would doubtless be distinctly different, as the yellowed lens would act practically as a pale yellow screen. One often hears divergent opinions expressed as to the advantage or otherwise of using orthochromatic plates without a light filter, and it is remotely possible that the lens used may be a factor in the case, more particularly if it is one of early date.

\* \* \*

### Hot-Weather Precautions.

Gelatine in hot, damp weather is one of the finest breeding grounds for microbes, and is used largely by experimentalists for their "cultures" of bacilli. And the photographer finds that valuable negatives may be ruined by remaining overnight in a hot, badly-ventilated dark-room to dry. One of the commonest occurrences is to find that the surface of the negative is covered with small circular pits or holes, where the gelatine has apparently shrunk away from a central point, leaving a shallow depression, of decreased density, and has formed a circular wall or ridge of greater density round the pit. This frequently happens in the drying of a negative that has been washed for several hours. Sometimes there may be only one or two such marks, and these can be spotted out, but a negative may be so covered with them as to be useless. Thickly coated plates, more particularly when a soft gelatine is used, are most liable to this trouble. Fortunately, it can be prevented by several methods. The simplest way is to add chrome alum to the fixing bath about half an ounce or less to each pound of hypo. If the chrome alum be added to the plain hypo solution a dense yellow precipitate is thrown down, which is difficult to remove from the surface of negatives; but if an amount of sodium sulphite, equal to, or, better still, in excess of the chrome alum, is first dissolved in the fixing solution, no precipitate will be thrown down, although the solution becomes a deep green colour. If a plate has been fixed in plain hypo, and has been washed so long as to be liable to "pitting," it can be saved by drying quickly with spirit, or by placing in the current of air from an electric fan, or it may be soaked in a dilute chrome alum solution, washed again for five minutes, and dried as usual.

\* \* \*

### A Congress of Photographic Record.

We learn from the Permanent Commission of the International Congress of Photography that a conference is to be held at Marseilles in October, at which are to be discussed questions relating to any or all the applications of photography to documentary purposes. The idea of a conference appears to have emanated from the "Musée des Photographies Documentaires" in Paris, and, acting under this stimulant, the Permanent Commission now proposes to prepare a list of photographs of a "survey," or "record," description, to organise the preparation of other such photographs, and to bring together persons interested in the work. There must be many people of leisure who would be glad to take part in such a scheme as the above, which, it is to be hoped, will bring the French organisation into touch with the National Photographic Record Association, and who may desire to address the President of the Commission, General Sebret, at 51, Rue de Clichy, Paris.

**rumours of colour photography.** "So far photographers have only succeeded in producing the effect of colour in photographs by means of three negatives taken through colour screens, from which positives are produced and dyed." This sentence, in Tuesday's "Westminster Gazette," emphasises once again the extraordinary ignorance of the lay Press of colour photography, an ignorance which is all the more regrettable, since colour photography is one of those subjects which the general Press cannot leave alone. Like moths round the candle, the newspapers are continually accomplishing the destruction of their technical reputation by the eagerness with which they dogmatise on the immense possibilities—occasionally it is the impossibilities—of colour photography. This time the "Westminster" will have none of a rumour that Dr. König has completely solved the problem of colour photography, and calls in a Mr. T. H. Williams to show that everyone is on the wrong track in attempting to arrive at colour photography *via* filters and pigments. But our author can hardly expect a patient audience of photographers when he sanctions the statement at the head of our paragraph.

### A PLEA FOR THE VIGNETTE.

FASHIONS change in regard to photographs as they do in most other things. At one time full-length portraits and vignettes were about the only styles that met with general favour. The former, of late years, has been greatly superseded by three-quarter lengths and heads and busts. The vignette, it is true, is still in some demand, but its popularity is decidedly on the wane, and we learn that some of the leading houses are now seldom asked for it. One cannot help feeling some little regret at this, as a vignetted portrait is, after all, a very pretty style of picture, provided the vignetting is skilfully done and a suitable background employed. Some of our older readers will be able to recall to mind the exquisite vignetted portraits that were produced by the late Mr. T. R. Williams, of Regent Street, also by Mr. Mullins, of Jersey, and one or two others, many years ago. These were quite different from the present style of vignette. They were mostly of the whole-plate size, and were principally three-quarter lengths or more. The pictures were excellently vignetted, and were quite of a light, sketchy character, and widely different from the present pear-shaped head and bust vignette, which is often taken with a dark background.

Some wonder may be expressed at the fact of the vignette dying out for small pictures while it is still so much in favour for enlargements. One reason probably is that the former, of late years, have been so unskilfully and inartistically executed. If one takes a well-finished vignetted enlargement with some well-marked hatched cross-lines about it, and reproduces it of a small size—say, cabinet—it will be seen how much superior it is to a direct vignetted print, as so frequently seen. It will be noticed that the shading or vignetting is much better graduated than that of the everyday (so-called) vignetted print, and that the hatched lines add very materially to the effect.

Some years ago the late Mr. Napoleon Sarony introduced and patented a method of producing vignetted portraits that was very effective. Instead of the usual plain pear-shaped vignette, the picture resembled the famous Richmond heads, on a small scale, by having hatched lines introduced in the shaded-off portions, chiefly at the lower parts. This was in the *carte-de-visite* days. There were two methods of producing these results. One was by

first printing the vignette in the ordinary way and then printing in (by double-printing) the hatched sketchy lines from a second negative. This negative was copied from the sketched lines in chalk or pencil, made on a somewhat large scale. Another method was to produce the hatching and vignette on the negative itself in the camera so that the effect was obtained without the trouble of double-printing. In the camera, at a suitable distance between the lens and the plate, was placed a vignetting mask admitting only such portions of the figure as were desired to be shown in the finished picture. After the exposure for the portrait had been made, this mask was removed and another, which was the reverse of the first and contained the scroll or hatched lines, was substituted, but this mask was put quite close to the plate, so that it was fairly well within the focus of the lens, and then a second exposure was made to a sheet of white card or paper. An alternative method was to place before the first exposed part of the plate a reverse of the mask then used and make the second exposure direct to the scroll or hatched drawing. By either of the latter methods the finished picture was obtained by a single printing, and with less trouble than is entailed in the ordinary methods of making this class of picture.

Speaking of vignetting in the camera, it may be mentioned that this was the first method of making vignetted portraits. Daguerreotypes and glass positives used to be produced in this way. The method usually adopted was as follows: The sitter was posed before a rather light background, and between him and the camera was placed a large white screen, with an opening with serrated edges. This screen was placed at such a distance from the camera that it was quite out of the focus of the lens, while only so much of the figure as was desired to be shown could be seen through it. The portrait was then taken, and the result was an exceedingly pleasing picture, particularly if it were a glass positive and was whitened by what was then known as the alabastrine process.

Many of our older readers, again, will remember the pictures shown many years ago in one of the Photographic Society's (now the Royal) exhibitions by a Russian photographer—Bergamasco by name. At the time these pictures were exhibited they created quite a flutter in English photographic circles. They were large in size, being something like fifteen by twelve and larger, the heads being some four or five inches long, and were all very boldly lighted. They were direct pictures, and were vignetted into dark or rather black margins instead of the usual white ones, which gave the faces extraordinary brilliancy and relief. At first the method by which they were produced was treated as a secret one, but it was stated subsequently that they were made direct in the camera by placing a suitable vignetting form at a certain distance between the lens and the plate, so that the margins of it developed as clear glass. In printing the latter was sometimes shaded so that they were slightly graduated instead of being one uniform black mass. A few photographers here attempted to produce these pictures—mostly in smaller sizes, with but more or less success, the latter rather than the former—and, as a result, the style did not prove a commercial success in this country at that time. Recently we have seen pictures of this type in small sizes, but they have all been of a very mediocre character, and not at all likely to take with the public, though we see no reason why they should not if they were more artistically produced and of a fairly large size, for, in our idea, this class of picture is not well suited to pictures of small dimensions.

The object of this article is to call attention to the decadence of the vignette, with the view to stimulating

photographers to give greater attention to it by making the pictures of a more artistic character than is now the case, say, by introducing something like the hatched or scroll effects of Sarony, or anything else that will give a novelty to the work. In passing, it may be mentioned that the hatched effects are far better adapted to cabinet size portraits than they are to the carte-de-visite, the

size in vogue when this style was introduced. It does not follow that an idea that may in reality be old would not be a novelty if reintroduced. It would be a pity, I think, if the vignetted portrait were to become obsolete for it is a very excellent picture when skilfully produced, and, what is not unworthy of consideration, it commands an enhanced price.

## THE PRINCIPLES OF DIRECT COLOUR PHOTOGRAPHY BY PRISMATIC DISPERSION.

(A Paper read before the Paris Academy of Sciences.)

In order that a photographic print shall reproduce all the colours of the original, two conditions must be fulfilled:—

(1) The sensitive plate should preserve the slight differences which exist between the different radiations which occur in the incident light; it should, in other words, analyse each incident ray of light.

(2) To reconstitute the incident light in colour at one operation, the system should be reversible, so as to effect synthesis from the elementary colours.

Following from this general statement, we may ask whether any physical phenomenon which permits of two elementary colours being distinguished cannot be made to serve as the principle of a system of direct colour photography. Such a phenomenon, for example, is prismatic dispersion, as it occurs in a spectroscope, and does actually supply a solution of the problem of direct photography in colours.

A photographic spectroscope consists essentially of a slit,  $f$ , a prism, a lens, and a sensitive plate. It determines the analysis of the light which falls on the slit. It can be shown that the apparatus is reversible, and that it is able to re-compose the coloured light falling on the slit.

Suppose that the sensitive plate has been developed, and that a positive from it has taken its place. If the slit has been lighted by red rays, these rays will give in the spectrum an image,  $r$ , of the slit. This image (transparent in the positive) forms a kind of slit which, on the plate being returned to its position, is the conjugate image of the slit,  $f$ . Inversely,  $f$  is the conjugate image of  $r$ , according to the principle of the inverse course of rays. This double condition is satisfied for the red rays which have formed the image, and for them only; rays of any other refrangibility would have a different course, and would fall on neither  $f$  nor  $r$ .

Hence it follows that if  $f$  is illuminated with white light, the transparent region  $r$  receives only the rays which have formed it, and only allows these latter to pass. If the light be made to pass in the opposite direction—that is to say, if the positive transparency is lighted with white light—the slit receives and allows to pass only the rays which have come from  $r$ .

This reasoning is applicable to rays of any refrangibility, and to rays existing simultaneously with others. In other words, the photographic positive being in position and exposed to white light, the slit receives a light of precisely the same spectral composition as that which fell upon it during exposure. If the negative is substituted for the positive transparency, the slit is illuminated by the exact complementary of the light which is received during exposure. In this case, the portion  $r$  occupied in the spectrum by a given set of rays is an opaque area. These rays, therefore, cannot reach the slit, since the only rays of this kind which would be able to fall on the slit are those which would have passed through  $r$ . In short, with a transparent positive photograph in the

position of the spectrum, the only rays to pass are those which acted during the exposure; these rays are replaced by their complementaries if the negative is substituted for the positive.

In order to apply this principle to the reproduction of colours, I have arranged the following apparatus:—Instead of the single slit of a spectroscope, I use a series of slits all very close together. They are fine transparent lines of a ruled screen of five lines per mm., such as is employed in photographic reproduction. This screen is fixed to the front of a photographic enlarger, i.e., to a box provided at its extremity with a sensitive plate, and carrying a converging lens about the plane midway between its two ends. In front of the lens I fixed a prism of small angle, with its edge parallel to the transparent lines of the screen.

The image to be reproduced is projected on the screen; the sensitive plate is developed and put back in place. On illuminating the apparatus with white light an image is seen in colours. Each line of the screen acts as the slit of a spectroscope, and, as the lines are not visible at the distance of distinct vision, the image appears continuous.

The first experiment on these lines was made with the spectrum of the electric arc, which was reproduced in colours by means of a positive transparency. When a negative was used the red was replaced by its complementary, blue-green, and the green by purple. A red and green stained glass window applied to the screen was likewise reproduced in its colours, and afterwards in its complementaries.

It is necessary that the prism fixed in the apparatus shall have an angle so small that each spectrum has a length less than the interlinear space, otherwise the spectra encroach on each other. It is also essential that the photographic plate occupies exactly the same position as during exposure, a condition which is easily fulfilled in the case of solidly constructed apparatus. If the positive is moved in its frame, the colours rapidly change; if it is turned, there is a coloured moirée effect. On bringing the plate back to its original position these effects disappear.

Rapid commercial orthochromatic plates may be used, and the exposure is much shorter than in the interference process.

On the other hand, it is not at all convenient to have to put the positive back in the apparatus whenever it is desired to see the colours. Examined in the hand, the positive is black and white, just like an ordinary transparency. Viewed with a lens, it is seen to be broken up into lines, each line divided into small zones, which are the parts of a spectrum.

It will perhaps be possible to improve this process so as to avoid the use of an apparatus to observe the colours, and to make the plate sufficient in itself.

Suppose that a sensitive plate be placed in an ordinary camera, without a prism, but with the interposition of a ruled screen, and suppose that on the screen (which, we will

ay, has 5 lines per mm.) we superpose a grating of 500 lines per mm.; each luminous point thus projected on to the screen then spreads as a spectrum, and is photographed. On applying the screen, with its grating, to the developed positive, we

The following note is also communicated to the Academy of Sciences:—

### A NOTE ON THE THEORY OF THE INTERFERENCE PROCESS OF COLOUR PHOTOGRAPHY.

is the theory which I have set forth of the photography of simple and compound colours, I have confined myself to the particular case of plane waves. But in practice the waves are not plane; they are appreciably spherical, since the plate receives the projection of points. It is, therefore, well to put the theory in correspondence with practice, an operation which leads us to the conclusion that theoretically we may replace the mercury mirror by other devices.

I will assume the perfect objective, giving an image P (reduced to a point), of an external point. The point P and its image, P<sup>1</sup>, given by the mercury mirror behave as two synchronous sources. The interference fringes (with one exception) are not plane, but have the form of hyperboloids, with P and P<sup>1</sup> as foci. These are the fringes which are embedded in the sensitive film in the form of silver deposit possessing a feeble reflecting power.

Suppose the films are formed by light of wave length  $\lambda$ , and that we cause white diffused light to fall on the plate. Any incident ray whatever which passes through P cuts the series of hyperboloids, corresponding to the maxima of the light, in a series of points, M, M<sup>1</sup>, M<sup>11</sup>. . . . and the straight lines MP, M<sup>1</sup>P<sup>1</sup>, etc., are equally inclined to the surface of the hyperbolic fringe. Thus the corresponding reflected rays make part of a conical bundle, with its apex in

should see the colours of the original—that is to say, if the eye can occupy the place of the lens. The optical system, as explained in the earlier part of the paper, is reversible.

GABRIEL LIPPMANN.

P<sup>1</sup>. Moreover, the reflection is selective, that is to say, it affects only the rays  $\lambda$ , which form the system of fringes.

Thus, when one passes from a point M to a point following in the series, the "difference de marche" between the two reflected rays increases from  $\lambda$  the difference of the corresponding phase is equal to zero if the incident ray has the wave length  $\lambda$ , and only so in this case. The only vibrations reflected appreciably are those which have formed the bundle of interference fringes.

In the above demonstration, P and P<sup>1</sup> are two synchronous sources, images of the same distant point, and there is nothing to imply that the point P<sup>1</sup> should be obtained by reflection in a mirror. It may therefore be concluded that the system of these two sources may be obtained by means of any of the devices used for producing interference fringes, such as a bi-prism or a double Fresnel mirror, fixed before the lens.

Theoretically, we may replace the mirror by any one of these systems, but practically it is not possible, for the points P and P<sup>1</sup> should be close together, and this condition is not fulfilled in the case of the bi-prism or the Fresnel double mirror. There is no doubt that the system of two semi-transparent mirrors is the only one likely to be successful experimentally.

GABRIEL LIPPMANN.

## THE TONING OF BROMIDE PRINTS.

The following notes conclude the extracts from the recently published work by Dr. E. Sedlacek on the principles of the processes employed in the toning of bromide prints. For the full text of the author's experiments and conclusions the original German work, published by W. Knapp, of Halle a/S., should be consulted.

### The Copper Process.

Whilst with iron and uranium the ferri-cyanides are soluble and the ferrocyanide insoluble, in the case of copper the ferri-cyanide is insoluble. The correct proportions of sulphate of copper CuSO<sub>4</sub>·5H<sub>2</sub>O and potassium ferri-cyanide are as 4:3. The correct way to mix copper toning solutions is to add an organic salt to the copper sulphate solution, and then add the ferri-cyanide. If the organic salt is added last much more will be required to dissolve the cupric ferri-cyanide.

The copper baths may be used in an acid neutral or alkaline state, but weak ionised acids must be used, if a highly ionised acid is used insoluble copper salts are precipitated. An excess of an organic acid does not prevent the toning action, but it will frequently give rise to a fogging of the image by the formation of basic copper compounds. Care must be taken to avoid, too, the use of salts which easily form cuprous compounds, such as the sulphocyanides and bromides.

The tones obtained with copper stand the action of alkalis better than those with iron and uranium.

The following baths are recommended; as they do not keep well they should be mixed just before use:—

#### RED TONES WITH A BROWN TINGE.

Potassium citrate, 10 per cent. sol. ....	150 minims.
Copper sulphate, 10 per cent. sol. ....	24 minims.
Potassium ferri-cyanide, 10 per cent. sol. ....	18 minims.
Ammonia alum, sat. sol. ....	60 minims.
Water .....	1 oz.

#### BRICK-RED TONES.

Potassium citrate, 10 per cent. sol. ....	75 minims.
Copper sulphate, 10 per cent. sol. ....	24 minims.
Potassium ferri-cyanide, 10 per cent. sol. ....	18 minims.
Ammonium carbonate, 10 per cent. sol. ....	6 minims.
Water .....	1 oz.

This bath has a tendency to give double tones, that is, the deep shadows show a blackish tinge. A very beautiful cherry-red tint with a violet shade is obtained by replacing the citrate solution in above bath with quarter-oz. of 10 per cent. solution of ammonium oxalate, but the whites are often tinged.

#### RED-BROWN TONES.

Potassium oxalate, 10 per cent. sol. ....	60 minims.
Copper sulphate, 10 per cent. sol. ....	24 minims.
Potassium ferri-cyanide, 10 per cent. sol. ....	18 minims.
Tartaric acid, 10 per cent. sol. ....	6 minims.
Water .....	1 oz.

A faint tinge is imparted to the whites by this bath. If the tartaric acid is replaced by acetic acid a browner tone is obtained. If the quantity of oxalate is doubled, and 60 minims. of alum sat. sol. added to the above, a purer brown is obtained with tinged whites, which give the effect almost of toned papers.

#### COPPERY-RED TONES.

Ammonium oxalate, 10 per cent. sol. ...	120 minims.
Copper sulphate, 10 per cent. sol. ....	24 minims.
Potassium ferri-cyanide, 10 per cent. sol. ....	18 minims.
Oxalic acid, sat. sol. ....	6 minims.
Water .....	1 oz.

This gives a slight tinge to the whites.

In the baths containing an acid, variations may be obtained by using oxalic, acetic, tartaric, citric, or other organic acids; the first tends to red and the acetic most to brown tones, whilst the others are intermediate.

The prints should be left in the baths till the desired tone is reached, and then thoroughly washed; the duration of washing is without influence on the tones, as the copper salts are stable.

Very pleasant warm brown tones are obtainable by treating the toned prints to a weak ferrous oxalate developer for a short time, not too long, or dirty blue tones are obtained; such a developer is:—

Ferrous sulphate, 10 per cent. sol. ....	$\frac{1}{2}$ oz.
Potassium oxalate, 10 per cent. sol. ....	$1\frac{1}{2}$ oz.
Citric acid, 10 per cent. sol. ....	24 minims.
Water .....	1 oz.

Brown tones are also obtainable by treating the toned prints with the acidulated sulphide bath given above (B.J., August 10), or a 0.5 per cent. solution of sodium sulphide.

Considerable information is given about the lead toning baths and the many variations that can be played on the same; but as the results are by no means satisfactory, and the details would only interest those who delight in chemical acrobaticism, this part of Dr. Sedlaczek's work has been passed over.

#### Indirect Toning Processes.

The simplest of all the indirect toning processes is that in which the silver image is converted into a colourless silver compound, which is then reduced to a coloured salt. There are methods, however, in which the conversion of the silver plays only a secondary part, and in which it does not give the coloured product. Then there are processes in which other metallic salts, such as those of copper or mercury, are added.

It is essential to differentiate between pure halogenising mixtures and those in which oxidation first takes place with subsequent halogenisation. Thus chlorine water belongs to the former class, whilst bichromate and hydrochloric acid to the latter, for it contains no free chlorine but free chromic acid, which oxidises the silver, and this is converted into chloride. If permanganates are used, practically the same action takes place, although the line between halogenisation and oxidation cannot be so sharply drawn.

Aqueous solutions of the halogens can be used, and chlorine water acts the quickest, bromine water slower, and solution iodine in iodide so slowly as to be practically useless. The advantage of these reducing solutions is that they have no reducing effect on the prints.

#### The Use of Oxidising Solutions.

The chromates and permanganates should be used; the hypochlorites are out of court, because they attack the gelatine, and hydrogen peroxide and the persulphates act too slowly.

It is frequently noticed that solutions of bichromate and sulphuric or a chloride reduce the image, and this is due to the fact that the silver is converted into the oxide or soluble sulphate at a quicker rate than these are converted into the insoluble chloride. The best composition of a bath is therefore one containing hydrochloric acid and a soluble bromide, which thus retard the formation of the silver chromate, which is soluble in chromic acid, and also thus quicken the conversion of the oxide or chromate of silver into the insoluble halide.

If a permanganate is used, either with or without an acid, and ammonium chloride is also used, the reaction that takes place between the silver oxide and the chloride is expressed in the following equation:—

Peroxide of manganese is precipitated with the silver chloride,

but it can be readily dissolved by weak sulphite, oxalic or phurous acids. If an organic developer is applied reduction takes place, as the sulphite in the developer dissolves the silver chloride before it is developed.

If such images are to be converted into silver sulphide solution of sulphuretted hydrogen acidulated with hydrochloric acid should be used, and then the manganese is dissolved thus:

As the permanganates are more easily decomposed than chromates, acetic acid and an alkaline halide can be used with advantage; and then, with potassium bromide, free bromine exists in the solution; if, on the other hand, the ammonium chloride is used, there is no free chlorine, which is due to the fact that the weakly-ionised acetic acid cannot set free a considerable quantity of the highly-ionised hydrochloric acid.

The addition of the halide acids to permanganates always causes the evolution of the halogen, but they differ from the ordinary solutions of the latter in that they are in state of nascent.

#### The Ferrocyanide Processes.

A mixture of a ferricyanide and an alkaline halide produces instant conversion of the image into the corresponding silver halide. Such solutions can be kept as stock solutions; they do not reduce the image, nor attack the gelatine.

The bleached image can be readily converted into sulphide or sulphoantimoniate or sulphostannate of silver.

To convert the image into the sulphide, Dr. Sedlaczek is strongly in favour of sulphuretted hydrogen, and as strongly condemns sodium sulphide, and the latter because of the difficulty of keeping the sodium sulphide solution and the liability of the formation of unpleasant coloured polysulphides.

The conversion of the silver into ferrocyanide is not a quick process, probably because each silver grain becomes coated with ferrocyanide, which stops further action. Nitric and sulphuric acids, or a silver ferrocyanide solvent, such as an oxalate may be used.

Ferrocyanide of silver can be converted very readily into other compounds, and a great variety of tones may be obtained by using also other metals. It is unnecessary to enter at length into the chemistry of these processes, because the practical results are given below.

The bleaching bath for the print, which should be previously well soaked in water, should be:—

Potassium ferricyanide .....	6 grains.
Potassium bromide .....	$2\frac{1}{2}$ grains
Water .....	1 oz.

The image bleaches instantly, and should then be well washed and treated with the sulphuretted hydrogen bath (see the acidulated sodium sulphide bath given above), or ammonium sulphide or sodium sulphide, and for the latter the bath should be:—

Sodium sulphide .....	50 grains.
Sodium sulphite .....	50 grains.
Water .....	1 oz.

For use, one part of this should be diluted with nine parts of water.

It is important to wash out the bleaching bath before sulphiding, and sodium sulphide is the worst thing to use, because it gives rise, as already mentioned, to unpleasant yellow tones when the solution is stale. If a 1 per cent. solution of Schlippe's salt be used instead of the sulphide, brownish-red tones are obtained.

#### Toning the Ferrocyanide Images.

The bath for bleaching should be:—

Potassium ferricyanide, 10 per cent. sol. ....	$\frac{1}{2}$ oz.
Potassium oxalate, 10 per cent. sol. ....	$\frac{1}{2}$ oz.

When the prints are bleached, wash well, and by treatment with following solutions to obtain the various colours:—

Sulphuretted hydrogen, ammonium sulphide, or sodium sulphide, as previously given, result in violet brown tones. The tint of the prints tends more to violet or grey than that of the bromide bleached prints.

A 1 per cent. solution of Schlippe's salt gives reddish-brown tones, which are redder than the bromised prints thus treated. A red brown is also obtained by using—

Uranium nitrate .....	18 grains.
Potassium bromide .....	9 grains.
Water .....	1 oz.

Blue tones are obtained by treatment with—

Ammonia iron alum .....	12 grains.
Potassium bromide .....	6 grains.
Hydrochloric acid .....	2 minims.
Water .....	1 oz.

If in this bath the whites turn yellow, they should be well washed with a 0.3 per cent. solution of hydrochloric acid.

#### Toning with Mercury Salts.

In this, as already pointed out, the image is bleached with a mercury compound, and the bath should be—

Mercuric chloride .....	6 grains.
Potassium bromide .....	6 grains.
Water .....	1 oz.

When thoroughly bleached, wash well, and then treat with the following solutions to obtain the various colours:—

Greyish black, a 1 per cent. solution of hypo.  
Greyish violet, immerse in—

Hypo .....	5 grains.
Acid sulphate of soda .....	2½ grains.
Water .....	1 oz.

Brown to violet black:—

Hypo .....	9 grains.
Copper sulphate .....	9 grains.
Water .....	1 oz.

If to the above a drop or two of a 10 per cent. solution of sodium carbonate be added, the tones are darker.

Brownish-violet:—

Hypo .....	6 grains.
Silver nitrate .....	2 grains.
Acid sulphate of soda .....	3 grains.
Water .....	1 oz.

Blackish-violet:—

Treat the print with a 1 per cent. solution of acid sulphite of soda.

## SOME NOTES ON READING AN AMERICAN MAGAZINE.

THE other day the writer came across an old number of a magazine, new to him, and probably new also to most of the readers of the *B.J.*, bearing the name, "The Munsey." Although it is priced in English currency and a London address is given together with that of one in New York as that of its offices, it is palpably of Transatlantic origin, as most of its matter relates to American subjects, and all its advertisements are of American offerings. It so happens that this particular number contains much that is of interest to anyone connected with photography.

#### Four Portraits.

One article is devoted to a comparison of the four portraits of a lady, a Mrs. Philip M. Lydig, who is presumably one of New York's most beautiful women, excellent reproductions being given of a photograph by Reutlinger, of Paris, a dry-point etching by Paul Hellen, and paintings by Boldini and H. J. Thaddeus, all of which have been made during the last two years, and yet the four are so dissimilar as to lead the observer to think that they cannot possibly be of the same subject. After describing Mrs. Lydig as she appears to him, the writer, a Mr. Ralph Donaldson, proceeds to criticise the four portraits, and to those who are familiar with the preachings of certain would-be leaders of photography, it is a relief to find good, straightforward, professional photography favourably compared with the work of recognised artists.

#### An Excellent Likeness.

Says Mr. Donaldson:—"The photograph, as seen by other eyes than that of a painter, is an excellent likeness of Mrs. Lydig. It is as thoroughly lifelike as photography can be. No one knowing her could possibly mistake it for the picture of some one else. It does not flatter her; neither does it detract from her, save as inaction must of necessity detract from one of sparkling vivacity.

With every one except the artist and art critic, likeness is the essential, the vital thing, in a portrait; and that quality we find in this bit of the camera's work. Such a portrait of any one would be pronounced good by the world. But would the world be right or wrong? If right, how about the merit of these three other portraits, which bear almost no resemblance to the photograph? Neither do they bear any resemblance to one another.

A portrait, to the artist, is a work of art, not simply a reproduction of pose and features. Mere photographic likeness he scorns. It is the man himself he portrays—the inner life, not the outer shell. To his eyes temperament, character, spirituality or grosser nature,

strength or weakness, refinement or brutality, are seen as no one else can see them."

Mr. Davidson goes on to point out how "Thaddeus has seen Mrs. Lydig with the eyes of an Irishman, and has made her substantially robust. Boldini, viewing her with the eyes of a Parisianised Italian, has represented her as not very substantial. And not only do the two canvases show slight physical resemblance to the subject as she appears in a photograph, but as depictions of character they differ no less widely from each other and from the word picture—which is as faithful as the writer can make it—given in these pages. The Thaddeus painting lacks the sparkle, the brilliance, the vivacity that are such salient qualities of its original; while her thoroughly sane, normal, modern humanity is not shown in the Boldini. The latter is certainly a remarkable interpretation, and one that pulsates with art and art feeling. But for the real Mrs. Lydig one must go back to the portraiture of the camera."

#### American Portraiture.

An appreciation of Henry Wattersson, who is described as "the most striking and interesting personality in the American journalism of to-day," is illustrated by a very fine full-page half-tone of a half-length portrait with the imprint, "Strauss, Louisville." The name Strauss has been mentioned several times recently in the *B.J.*, but always in connection with the St. Louis studio. Possibly there is a relationship. The portraits throughout the magazine are almost all good. In an article on "The Jews in America," seemingly by way of adding variety to the appearance of the pages, the photographs have not been reproduced direct, but drawings have been made, and from them line blocks which are printed in black on a cream ground. The photographer is credited with his share by the acknowledgment taking the form, "Drawn from a photograph by —," and it is interesting to note that although the portraits are in every case those of leading men, out of seventeen such acknowledgments only two state that the photographs are copyright. It would appear from this that the copyright regulations in the United States differ considerably from those in this country.

#### American Advertising.

The advertising portion of the magazine makes interesting reading. In America seemingly almost everything is "taught by mail," dancing, music, law, nursing, pharmacy, advertisement-writing, being but a few of the subjects in which instruction may be had. With

photography it is different; it appears that attendance is necessary, for one advertisement runs: "Attend the Illinois College of Photography. A delightful profession, quickly and easily learned. Pays well. Good positions secured for graduates. Only College of Photography in the world. Terms easy and living inexpensive. Write for our beautifully illustrated catalogue. Address, etc., etc." The adjective delightful is distinctly good; it supplies just that amount of vividness to the charms held out necessary to finally convince the hesitating reader. Possibly one of the reasons for photography in America being so delightful, is to be found in the fact that nearly all the advertisers who are willing to help their fellow-creatures in various ways, head their advertisements with portraits, presumably of themselves, as if to say, "Can you imagine me making a statement that is not strictly true? Is not my face a guarantee for my veracity?" The advertiser who offers to "double your salary" by teaching you advertisement writing; the doctor who advises you when you travel to be sure to take his liniment; Gordon, who "makes suspenders" (Anglice, braces), which he is willing to send free on approval to any business man, are among those who thus use their photographs, while the lady who takes a full-page in which to tell her fellow women that she can make them "well, strong and beautiful" (by mail, of course), has two photographs of herself with which to add weight to her announcement.

#### Photographs in Advertising.

Photography, it should be said, is employed to better purpose in many of the advertisements; in fact, in some of them, a photograph with a little descriptive lettering upon it, constitutes the whole advertisement. Thus a page is taken by a milling company with a most effective photograph of a number of barrels and bags of flour with the brand thereon

showing up well, and in similar style is the soap advertisement the effect that "A child can do the work," the photograph being that of a child who is washing a toy lamb. A railway company uses eight picturesque views—different advertising from that of our railway companies. Good use of a photograph is made by a rubber-tyre company, a design in the form of part of a wheel having the space between two of the spokes filled with a photograph of a busy street showing a row of cabs and carriages, the spaces above and below containing the descriptive matter. It is certain that our own advertisers will soon be using photographs to the same great extent as the Americans are now doing, and although it is rather outside the province of the ordinary photographer, an opening is indicated for the man who is anxious to add extra branches to his existing business.

Such are a few of the impressions formed by the present writing upon reading the January "Munsey."

#### A Comparison.

One word more! The Henry Watterson already mentioned contributes a comparison of American and British newspapers much in favour of ours. He says that "English type-setting and English presswork, and English paper-making—better than with us—give the London newspapers considerable advantage over the American newspapers in appearance, while their make-up excels ours in system and order. None of the great dailies of London use display type as it is used in America. They affect book-work in their typography as we do in their composition. . . . These ethical principles are better understood and more often applied in England than in the United States. Frankness should beget frankness, and if the magazine on which these lines have been written be a fair average specimen of the American magazine, it must at once be admitted that in magazine production they are far ahead of us.

W. J. CASEY.

## THE LAWS OF THE STEREOSCOPE AND STEREOSCOPIC TRUTH.

(A paper read in the "Bulletin de l'Association Belge de Photographie.")

THERE is no subject which has given rise to so many contradictory ferent distances, and the dimensions of the same. It seems possible that photography is an indispensable assistance, it ought to be comparatively opinions, sometimes correct and often extravagant, amongst which it

#### Fundamentals.

Let us take any object in nature. What is true of it will be true for all the others.

When we look at an object we see it by the aid of those eyes which Dame Nature has given us and placed in their orbits at a normal separation of 6.5 cm. But, if instead of looking at the object itself, we consider its image reproduced by stereoscopic photography, we can see our object under quite different conditions from those in nature, for the simple reason that when photographing it our lenses may be separated in a different manner from our eyes.

We can undoubtedly:—

1. By keeping the distance of the camera from the object constant, but by changing the separation of the lenses, vary the angle of convergence of the visual rays; that is to say, we can see the object as will presently be shown, as though our eyes were either more or less separated than they actually are. We may see nature as though we had the eyes of an ant, which are but slightly separated, or as though we had the eyes of a mammoth, which are separated by more than a metre.

2. By varying the distance of the camera from the object we may reproduce it as though we saw it close at hand or at some distance, without altering the angle of convergence of the visual rays. To obtain this result, it is sufficient to diminish advisedly the separation of the lenses when photographing near objects, or to increase the separation on the other hand beyond the normal separation of our eyes when photographing at a distance.

We must not forget that the expressions "at a distance" and "near" apply to the distance at which we have first taken our posi-

theories as stereoscopy, that is to say, the vision of objects at distance with a little observation and experience, amongst which photography is to disengage the laws of stereoscopy from amongst the chaos of is now entangled.

tion to examine the object which is later photographed, and to the angle of convergence of the visual rays which is the result of this distance. It must not be forgotten, above all things, that what we shall say applies only to binocular vision. If only one eye be used one cannot estimate either the distance or dimensions of an object, without shifting the head to the right and then to the left, so as to obtain the impressions of perspective which are produced by changing the point of view. But this is no longer stereoscopy. The possibility with an immovable eye, of approximately estimating the distances, is because we know beforehand the dimensions of the objects looked at; the mind then jumps at the distance by the apparent dimension in perspective.

3. In separating more or less the two elements of the stereoscopic photograph, we can alter the angle of convergence of the eyes which look at them.

To enable the importance of these preliminary remarks to be thoroughly grasped, it may be useful to explain at first, by means of an experiment, and then by a design. The experiment may be performed by direct vision; the design requires the use of a stereoscope. The two will prove first the truths, the confirmation of which we shall demand from photography.

A. The experiment by direct vision is that one must learn to squint a little; this is one of those useful things which one learns at school, without the aid of the master. If the reader's education is incomplete in this respect, he should try to see the end of his nose, and he will soon be *au courant* with the present requirements. Moreover, he naturally squints in a constant fashion, less when looking at infinity, the only case in which our visual rays do not converge to the point at

which we look. But the word "to squint" means really convergence of the optical axes without looking at any fixed object.

Consider the following diagram (Fig. 1).

You will see a series of white dots, of which two have black centres. You may exactly estimate the dimension of these dots and their distance from your eyes. In passing over all the points of sight, your angle of convergence does not change: it is that which gives you the notion of their distance, unconsciously but surely, from which your mind concludes as the result of continuous experience which it has given in the sense of sight.

The idea which you make of the size of the white dots results from the space that their image occupies on your retina, it being granted

centre on the right; these two points will superimpose, and the entire image will take for a moment the following, seen in Fig. 2.

But at the same moment you will note at the same glance that all the points have approached nearer to you, and that they, at the same time, have become smaller. The contrary effect may be obtained if, instead of squinting by crossing the convergence, you diminish it. In effect the path of the visual rays becomes as follows.\*

Supposing in Figs. 3 and 4, which follow, the white dots of the above diagrams are represented by the lines numbered from 1 to 6. The eyes should first look normally at the centre P of dot Number 4. The angle of convergence G P D has given to the mind the appreciation of the distance of the point P from the eyes G D. Let us now

Fig. 1.

Fig. 2.

that the distance at which you see them is fixed. One cannot obtain an idea of the size of an object, if one has not at the same time a visual notion of its distance which is given by the angle of convergence of the visual rays. The estimation of this distance becomes the more difficult the greater the distance of the object; that is to say, it becomes more difficult as the angle of convergence becomes smaller or more acute. If the angle of convergence is nil, if the visual rays are parallel, all exact conception of distance and dimension becomes false. The gigantic sun appears to us larger or more distant than the moon, our neighbour, which is quite a negligible quantity, beside it.

Having grasped these facts, consider again the above diagram, this time with a slight squint. Soon, the two eyes will not see the same white dots; they will superimpose two by two: for example, the right eye will see the central point on the left, and the left eye the

consider the case of Fig. 1. We have squinted slightly so that the right eye sees the centre O of dot No. 3, whilst the left eye continues to look at P; we have thus increased the angle of convergence, which will become G p D instead of G P D, which it was at first; from which the mind concludes that at the distance p D, where the two identical images, 3 and 4, are combined into one, at the distance they appear at p. But, however, this white dot p, which is mentally

\* We heartily commend to our stereoscopic readers a careful examination of these two diagrams in a stereoscope with adjustable eye-pieces. The effect with the second diagram is absolutely astounding. The number of dots can be reduced to eight or nine, the black centres may be made to disappear entirely, or be reduced to one, first on the right, then on the left; they may be reduced to two, not in contiguous circles, but in alternate ones or separated by two, three, or four. In the case of the first diagram equally extraordinary results are obtainable, and still further effects seen by varying the focus.—EDS. B. J. P.

brought nearer to the eyes, does not increase in diameter agreeably to the laws of perspective, but appears smaller than it actually is.

Fig. 4 supposes that instead of having increased the convergence it has been diminished—an experiment more difficult to perform than the former. The right eye continues to see the dot P, which the left eye has left to look at O. The first angle of convergence, G P D, is reduced and becomes G p D. It transfers to p D, the distance at which the mind believes it sees the image P<sup>1</sup> P<sup>1</sup> (composed of the

Fig. 3.

identical images 3 and 4), as though the images of all the other points were superimposed two by two. But all these white dots seen thus at a greater distance that they actually are, appear larger than they are; because they are located at a greater distance than their diameter, suffering from proportional diminution according to the laws of perspective.

This experiment has been described because we are convinced that very few readers are aware of it, and they will be surprised at the illusions produced. There should be no reason to doubt the truth of our statements, for they may be very easily verified in a stereoscope. Let us take the example given by M. Marteau in his stereoscopic notes, the conclusions in which we cannot agree with.\*

Fig. 4.

visual rays. This convergence ought to be greatest when examining the lowest rectangles, and less when looking at the upper figures which are the more distant the one from the other. If this couple examined in the stereoscope, although the rectangles have exactly the same dimensions and are situated at the same distance from the eye, the mind, as the result of experience, will produce an erroneous effect and one will believe in the existence of three plane rectangles of equal dimensions, placed vertically at three different distances in space. Where the angle of convergence of the visual rays is greatest, the subject is closer and diminished; where the angle is smallest the subject is further off and enlarged. Every observer must have the same impression. It will be sufficient for the moment to state this fact; later, we shall prove the mechanism of it.

### The Laws of Stereoscopy.

After having made these fundamental remarks which contain indisputable experimental point, we ought to recognise the following four laws of stereoscopy:—

#### Natural Binocular Vision.

**FIRST LAW.**—When an object is looked at the conception of distance is the result of the aperture of the angle formed by the convergence of the visual rays.

**SECOND LAW.**—The idea of the size of the object is the result of the conception of its distance and the angle that the object occupies in space. The apex of which angle is found in the pupil of our eyes, or, in other words, the idea of the dimensions of an object looked at is the result of the conception of its distance and the space which its images occupy the retina of our eyes.

#### Stereoscopic Photography.

**THIRD LAW.**—In a stereoscope the eyes always see as though they were in the respective places of the two lenses at the moment of exposure.

**FOURTH LAW.**—The separation of the lenses at the moment of exposure determines the angle of convergence under which the solids photographed ought to be viewed in the stereoscope.

Fig. 5.

**B.—THE STEREOSCOPIC EXPERIMENT.**—Here (Fig. 5) are a couple of stereoscopic prints formed of rectangles actually of the same size, which are to be superimposed in the stereoscope two by two. As the rectangles are of unequal separation it is impossible to make the three superimpose without varying for each the angle of convergence of the

\* M. Marteau's experiments were performed with ordinary postage stamps, and they may of course be used in like manner here.—EDS. B. J. P.

**NOTE.**—The word "solids" is intentionally employed, it being intended that there shall be no question of stereoscopic vis-à-vis of a subject not having two dimensions, such as an etching, a design, etc.

To thoroughly grasp the third and fourth laws it is sufficient to take account of the fact that the stereoscopic effect is the result of the mental fusion of two different perspectives. Now, these perspectives arise from the two points of the view occupied by the lenses at the moment

of exposure. In the stereoscope the eyes always see then the two perspectives as if they themselves occupied the two places which the lenses occupied; that is to say, one has the exact reproduction of the lines of perspective of the object photographed when it is viewed under the angle of convergence of the two lenses, and at a distance at which these were placed.

Experience and custom which give us the idea of distances and dimensions, which were described in the two first laws, are peculiar to every species of animal endowed with binocular vision. These notions are the combined result of the use of the senses of sight and feeling. It is certain that the species which have a separation of the eyes different to ours estimate distances and dimensions as we do; that is to say, in conformity with reality. Although they may see differently from us, custom and experience guide them as they guide us. But if the mind could suddenly see nature with the eyes more or less separated than those of the species to which they belong, all conceptions of distance and volume would become immediately false. Stereoscopic photography enables us to prove the truth of what we have advanced, as we shall presently prove theoretically and experimentally.

### The Corollaries of the Stereoscopic Laws.

The corollaries to the first law are:—

1. *The greater the angle of convergence of the visual rays the nearer the object looked at appears in the mind of the spectator. If this angle is small, the object is localised in the distance.*

This results from the habit we have of forcing the convergence more in order to measure those objects which are near to us and attract our attention. When we look at near objects, the greater the convergence, and, according to our first law, the idea that we obtain of the distance is the result of this same convergence, from which experience we have learnt to estimate and recognise the distance of objects.

2. *If we could change the angle of convergence without changing the distance of the object, we should falsify the notion of distance; the appreciation of the dimension would also become equally false.*

According to the laws of perspective, objects occupy in space an angle which is greater the nearer they are to us; this angle decreases in proportion as the objects recede. Consequently, if we could falsify the idea of distance by augmenting the convergence of the visual rays, the objects would seem to approach without their images increasing, and would appear to us smaller than they are. Inversely, a diminished convergence localises objects at a greater distance without diminishing the image, and they would appear to us too large. (See the stereogram of the three planes previously given in the stereoscopic laws.)

### The Corollaries of the Second Law.

*If the angle of convergence remains constant, whatever may be the*

*distance of the object looked at, it may appear larger or smaller than in nature, but it will always appear at the same distance from the observer.*

In fact, according to the first law, it is the angle of convergence which determines the notion of distance of the subject. If the object is distant its image will be small, but if the object appears to approach it will have the appearance of being reduced. If, on the contrary, the object is seen with the dimensions which it has viewed at close quarters—but always under the same angle of convergence—the image on the retina will be larger, but the object will not appear to approach, though it will appear enlarged.

It will be immediately seen that the corollary of the second law is not like the rigorous consequence of the two corollaries of the first, and that these two laws and their consequences constitute an ensemble with which there is nothing to find fault. That we cannot give an exact verification is due to the fact that our eyes cannot change their separation. To this objection, which is quite just, we reply with the

### Corollaries of the Third and Fourth Laws.

1. *By means of stereoscopic photography we can see objects as though we had a separation distance between the eyes other than the human separation.*

2. *In stereoscopic photography, there is only one way of reproducing objects in their true proportions as seen at the distance which they occupied in front of the lenses at the moment of exposure; this is to photograph them with a separation of the lenses corresponding to the separation of the human eyes.*

In effect, the 6.5 cm., which separates our eyes, forms the base of a triangle, of which the apex is the angle of visual convergence, which is our sole guide for appreciating first distances, and, consequently, by deduction, volume.

One cannot raise the objection that it is immaterial what may be the distance at which one sees the object in the stereoscope, if the stereoscopic effect is satisfactory. Many stereoscopists reason thus, and base their theories on their illusions. But it is not sufficient that the stereoscopic effect is good; it is absolutely necessary that it should be true. This will be especially seen in the case of a stereoscopic portrait. Now, each time that the separation of the lenses does not correspond to that of the eyes, the objects will appear larger or smaller than in nature, and their distance, like their proportions, will appear false in depth.

One of my good friends, whom I hoped to convince of his error, showed me a stereogram, well made, and showing good relief. I believed that I saw an electric lamp hung on the rough trunk of an old oak tree. But it was a fine pearl which the jeweller had mounted in a shell to represent a small acorn, forming a pin; the bark of the tree was the material of the cravat in which the pin was stuck! The photograph was taken very close to two exposures, with a separation of the lenses of only three or four millimetres.

A. GODERUS.

(To be continued.)

## FOREIGN NOTES AND NEWS.

### Varnishing Lantern Slides.

M. Remond in a recent communication of the Société Française suggests the use of the celluloid varnish for protecting lantern slides from the effects of heat in the lantern, and states that when dry it is quite non-inflammable. The formula he suggests is:—

Commercial celluloid varnish	...	...	...	...	4 parts.
Absolute alcohol	...	...	...	...	1 part.

Apply as with collodion; drain off the excess and wipe the lower edge, and corner with blotting paper. Allow to dry in an horizontal position, and then pass the slide varnished-side down through the flame of a spirit lamp till all trace of moisture disappears. After this the slide can neither be damaged by the fingers, nor will any heat in the lantern hurt it.

### Indirect Catatypic Pigment Prints.

Although considerable interest was excited at the time of Ostwald and Gros' announcement of the catatype process, but little has been heard practically of the subject. A German patent has been granted for

the following process: a negative is made from a transparency on carbon tissue, supported on celluloid, and developed, and allowed to remain on its support. This image is then converted into a catatypic image; either by immersion in silver nitrate solution or by painting with the latter, and the silver is reduced by a developer; or the negative is soaked in solution of chloride of gold or platinum, and then treated with a suitable developer. For instance, the above pigment negative may be bathed with permanganate of potash solution, and it will then be actively catatypic as peroxide of manganese is formed in the film.

### Yellow Stains.

Professor Latner, in speaking of the staining of negatives by the use of developers containing insufficient sulphite, says that this is not a fog, but merely a compound of the developer, which is not removed by the ordinary acid fixing bath. It is not always possible to increase the quantity of sulphite in the developer, nor is it advisable to add too much to the fixing bath, as this hardens the negative too much. The real remedy is to thoroughly wash the negatives

between development and fixing; this entirely prevents any staining; mere rinsing of the plate is worse than useless.

### Why is the Top of a Wheel Fuzzy When Photographed?

Herr Josef Wara answers this question in the current number of the "Weiner Mitteilungen," and explains it with the following diagram. Assuming that the wheel revolves on its axle once in a second, it will take up four definite positions in every quarter of a second starting from a; at the end of the first quarter-second it will be at a1; at the end of the second at a2; at the end of the third at a3; and at the end of the fourth at a4. The spoke end designated b1, b2, b3, b4, will also take up the various positions shown. If the

movement of the axle is compared with the movement of the spoke, that of the former is equal in each quarter-second, whilst the end of the spoke moves less in the first quarter-second and more in the second, and so on, as shown by the dotted curve. The movement of the axle is in the first half-second 4cm; if the image of the wheel is about 8cm, the spoke end moves in the same period 3cm; in the second half-second the axle moves 4cm., and the spoke end 7cm. From this it is obvious that the end of the spoke moves quicker at

the top than the bottom, and this is why the top of the wheel is fuzzy.

### A Photographic Transit Instrument.

M. Lippman has communicated to the Paris Academy of Sciences a description of a photographic transit instrument devised by him to increase the accuracy of measurements. There is a telescope which follows the stars like an equatorial, and photographs them on a plate which it carries; there is a fixed slit, representing a meridian, through which light passes every second or at given intervals, and is conducted by a mirror and collimator, so that it imprints itself as a thin line on the plate. Since the plate is moving and the slit is fixed, there results a photograph of a field of stars together with a series of lines representing hour circles or meridians, the exact numeration of which corresponds to the instants at which the slit was illuminated—and the rest is measurement. The principle is easily intelligible, but after understanding it, one naturally looks for possible imperfections. The object of all such apparatus is to get rid of personal equation; but it is not clear that there may not be personality in the measurement of time on a plate, and also something akin to personality in the recording of the times of the exposures. In all determinations of absolute time, recourse must be had to a level or its equivalent, and in this case a scheme has been arranged to measure the error of verticality of the plane of light which makes the lines on the plate and corresponds to the meridian by photographing the image of the slit reflection from the surface of mercury as well as directly on the same plate. Some small difficulties in this have had to be surmounted; but some successful plates were presented to the Academy and the instrument seems promising.

## STUDIO ACCESSORIES.

THE professional photographer desirous of holding his position, keeping in the front ranks, and making his business a paying concern, must keep constantly before him the state of his studio accessories. Portraiture (writes "Wilson's Magazine") is primarily a matter of dress, and secondly of furniture. The sitters do their part in appearing before the camera adorned with articles of attire adapted to the momentous occasion, the photographer having thrust upon him the duty of providing an environment which shall not spoil the effect his clients desire to produce for their own satisfaction and the edification of friends.

### The Luxurious Style.

It is sometimes urged against the portraiture of our leading professionals that the furniture is too profuse, occupying so large a portion of the stage that the sitter becomes merely a detail, an afterthought, put in to supply the human element in a picture, which might be appropriately labelled: "Interior, with Figure." To the photographic purist, the "Art for Art's sake" man, this criticism may appeal; to the man of business it will be made in vain, being summarily dismissed as of no practical worth. With this view we entirely agree, confessing to some regard for a portrait containing a well-arranged selection of accessories. The photographer must please his clients, and when these are drawn from the upper classes—persons living in homes richly furnished—they require a portrait photography in harmony with such surroundings, desiring works having the air of wealth, of luxury, and it is thus in the interests of trade to meet the demand. In doing so the photographer violates no principle of pictorial representation, for in all times the artist has depicted his sitters in association with the things of their daily life. All artistic sentiment being against a duchess in a dairy, or a dairy-maid in a drawing-room.

### The Conventional.

Whilst it is necessary to keep the accessories in harmony with the social position of the sitter, it should not be overlooked that all classes are susceptible to a certain amount of flattery in this connection, being more pleased with a portrait giving them a social standing above, rather than below, that which they really occupy. In all cases the photographer, whatever may be the class that give him patronage, should be in advance, having accessories of a more

expensive and luxurious nature than his customers are likely to possess. Only in this way can he apply this very subtle form of flattery. He already flatters the features by retouching, and this latter device is flattery to the dress. In working along these conventional lines a difficulty of a technical character will arise, needing attention to be overcome. The furniture designed for household decoration is inconvenient for studio uses, not lending itself readily to photographic methods of composition and posing. It is too angular, possesses awkward scrolls, quite preventing the subject being brought close enough for securing a good effect. A small knob is sufficient to separate the sitter from a chair or table creating a lack of unity in the composition, making it a picture of two objects in place of the simple design intended. Photographers who have experienced this drawback are constantly on the watch for any article combining a good design with utility in studio practice, in this way renewing their stock. Attempts have been made in supplying accessories to suit professional purposes, not with much success, for, whilst quite adapted to that end, they diverge too much from domestic patterns. In a picture looking what they are—quite photographic. There is here a want yet to be supplied, a field is open for the furniture designer who is able to combine photographic utility with a pattern neither grotesque nor unusual.

### The Plain and Simple.

In general, professional portraiture must be conventional, the usual thing, the photographer, whatever may be his own desires or aspirations, being compelled to meet the demands of the public taste. In particular localities, however, a class exists who will patronise work departing entirely from popular notions. Novelty attracts, and the man with a strong personality can impress the public, lead them to support him, and acquire a taste for his own individual style. An effective portraiture will follow from discarding all accessories and paying close attention to expression, lighting, posing and drapery. Mrs. Cameron was one of the earliest of these unconventional types, though since her time others—such as those who model their work after the paintings of Rembrandt, Gainsborough, Reynolds, or Velasquez—have met with success. To abolish accessories is to give added importance to the background, it becomes the chief study, requiring every attention to make it harmonious with the style of the subject.

is for this reason that the above-mentioned painters have been so closely copied by the Cameronian type of photographer. To some tastes this simple portraiture is very agreeable, and, with the right man, and a fitting neighbourhood, enough patrons are secured to make commercially profitable. A few can even go beyond it, with work that approaches to the "soul-studies" characteristic of Watts. Mere sketches and suggestions in place of the clear, sharp, well-defined photograph. However interesting these productions may be, in the present state of public taste the demand for them must remain strictly limited, and the majority of professionals could not insist on supplying such work to their clients, and still retain a profitable connection. From a financial point of view it would be a distinct gain if expensive accessories could be abolished, since the charge in a business which they entail, not only in purchasing but in keeping in good condition, would go with them. This was impressed upon us on once visiting the studio of a photographer of this class, a well-known man, whose work is much appreciated; beyond a few backgrounds, painted by himself, some drapery and screens, his necessities were only of a nominal value. A scanty outfit, calling for little expenditure, reducing the cost of working expenses to a minimum, a consideration when competition is so keen as nowadays. Anything tending to keep down expenses without reducing efficiency being money saved. Here the business man must study his public, or it will economise his resources if he can rely on clients who are satisfied with a portraiture of the simple kind.

#### PHOTOGRAPHIC RECORD AT THE BRITISH ASSOCIATION.

PHOTOGRAPHY has not figured very largely in the proceedings of the British Association this year at York, but it is noteworthy that a special meeting, consisting of delegates of corresponding societies met to consider the assistance which will be given to, and desired from, the work of photographers who are applying themselves to photographic record. Mr. J. Hopkinson presided. He remarked that it was becoming more and more desirable to obtain a permanent representation of the features of our country, whether natural or the work of man, for at no former period had the destruction or mutilation of such features been more rife, and, paradoxical as it might seem, never before had so much interest been taken in their preservation. The sooner a systematic attempt was made to obtain and preserve a picture of everything that admitted of representation by the camera the better.

A paper prepared by Mr. W. Jerome Harrison, of Birmingham, was read by the secretary (Mr. F. W. Rudler). Photography, it was pointed out, gave us knowledge at first hand in a way which could not be given by artists. With proper knowledge and care the transcript of nature made by a lens was, as far as it went, infallibly correct. Mr. Harrison mentioned that there are a quarter of a million photographers in this country—including snapshotters—who could do useful work if some one would tell them what to do and how to do it. He suggested the formation of a small sub-committee to collect details as to the exact work which has already been accomplished or is in course of execution, to prepare and circulate printed matter having reference to the work of the survey, so as to make its aims and methods generally known; to endeavour to co-ordinate the photographic societies with the literary and scientific societies, so that both may unite in the work of the survey; to obtain lists of experts who would be able to advise upon such subjects as photographic methods, processes, and appliances, draw up county lists of objects and places to be photographed, and write brief descriptions of the objects photographed and draw up lists of reliable literature on the counties or other areas. The publication of series of prints of districts or subjects would be one of the best methods of popularising and making known the work of the survey. The movement, added the writer, had come to stay; it only needed co-ordinating and directing along the right lines.

During the discussion Professor H. H. Turner, Professor of Astronomy at Oxford, suggested that in addition to the ordinary photographs, stereoscopic photographs should be taken, from which they could, by calculations, ascertain the distances between various objects shown.

It was stated that it was now too late to appoint a committee

in York, but it was decided that such a committee should be appointed next year at Leicester, and several gentlemen were nominated to serve on this committee.

#### THE VALUE OF REGULAR CUSTOMERS' NAMES.

RECENTLY (writes Charles L. Lewis, in the P.A. of A. Annual for 1906), while conversing upon the subject of insurance with a man who does a large mail order business, I remarked that the company with whom my insurance is placed would not insure my negatives. He thought that very strange, and said: "You see that file there? Well, that contains ten thousand names upon which I have twenty-five hundred dollars' insurance. I value those names at fifty cents each." Then he went on to explain that the names were those who had either bought goods or inquired about them.

Now, if we photographers were to secure the names and addresses of all prospective customers who call to examine work and inquire prices, what a splendid list of names this, in addition to our daily register of sittings, would give us from which to secure future business.

Why should not the follow-up letters system be quite as effective in the photographic business as in any manufacturing or mercantile business? Any legitimate means of interesting the public, and securing their patronage, is good business.

This presents an immense field for operation and obviates any necessity for falling a victim to any of the schemes of clever sharks for getting photographs for nothing.

Various schemes worked upon the photographer have been a prolific source of income to many a man, who, without the easy pictures-for-nothing mark, could not make his salt.

To return to the subject: Go to your register, look it over, and see if there are not some names registered there which need attention—some person who sat and did not order as he might have done had he been better pleased; a memorandum made of some child whose mother said she wanted a colour picture some day; some lady who said her parents were coming to visit her soon, and they wanted a family group, etc.

With many of us, I doubt not, the first fifteen minutes' glancing over the register will suggest enough letters to keep the stenographer busy all day. Don't be afraid to ask your regular customers for sittings; you can do it with much better grace than you can strangers. This, with the proper attention to the suggested list of prospective customers, will keep the receptionist out of mischief and result in a large increase of good legitimate business.

## Exhibitions.

#### ANDOVER AND DISTRICT HORTICULTURAL SOCIETY.

At the recent exhibition on Aug. 6th the judges (Messrs. F. Marnier and Milman) made the following awards:—

Class A (Figure Studies).—Gold Medal, H. Holt; Silver Medal, Rev. E. G. Watts; Bronze Medal, T. S. Bloom; Certificate, H. Y. Summons.

Class B (Landscape and Seascape).—Silver Medal, H. Y. Summons; Bronze Medal, A. Roffey; Certificate (extra), H. Y. Summons; Certificate, Mr. Stratton.

Class C (Architecture).—Silver Medal, James Dunlop; Bronze Medal, A. W. Walburn; Certificate, H. Y. Summons; Certificate (extra), J. Dunlop.

Class D.—(Animal Studies, Flowers, Fruit and Plants).—Silver Medal, G. Dunn; Bronze Medal, C. H. Eden; Certificate, Rev. E. G. Watts.

Class E (Post Cards).—First Prize, Mr. Richardson; Second Prize, Rev. — Clarke; Certificate, Mr. Hilton.

Class F (Landscape or Seascape).—First Prize, Miss E. S. Best; Second Prize, Rev. E. G. Watts; Certificate, T. C. Beynon.

Class G (Architecture).—First Prize, Rev. E. G. Watts. Second Prize and Certificate not given.

Class H (Figure Studies).—First Prize, Rev. E. G. Watts; Second Prize, T. C. Beynon; Certificate, Rev. E. G. Watts.

Class I (Beginners' Class).—First Prize, Mr. Monger.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been made for Patents from July 30 to Aug. 4:—

**CAMERAS.**—No. 17,092. Improvements in photographic cameras. Thornton-Pickard Manufacturing Co., Ltd. George Arthur Pickard and Frank Shays, 6, Bank Street, Manchester.

**CAMERAS.**—No. 17,359. Improvements in focussing and exposing devices of photographic cameras, and in connection therewith, John Edward Thornton, Altrincham, Cheshire.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**DISHES.**—No. 16,111, 1905. The invention consists of a dish with the bottom composed of sloping surfaces radiating from the centre, such that the plate is easily and quickly removed, it being readily seized on one corner being depressed by the finger. Reference is drawn by the Comptroller of Patents to the patent 11,650, 1903, granted to Kodak, Ltd. Joseph Hutchinson, 119, Turner Lane, Ashton-under-Lyne, Lancashire.

**FLASHLIGHT.**—No. 18,422, 1905. The claims are for (1) a flash-lamp having a pan for the reception of the powder, which pan

Fig. 1.

is open at the sides, and provided with a contracted opening at the top, so as to direct the light upwards and laterally; and (2) ignition by fulminating caps. Takerari Aiyhma, 11, Fukuromachi, Kanda, Tokio, Japan.

Fig. 2.

**CINEMATOGRAPHS.**—No. 24,426, 1905. This invention relates to apparatus for producing moving pictures, and more especially to fire-proof magazines for combustible picture-bearing films and to a compensating device adapted for use in connection with the spool on which the film is to be wound after or as it is unreel, the compensating device serving as the driving device for winding the spool, and being so constructed that the relative speed of the winding spool is automatically decreased as the quantity of film upon the winding spool increases, the speed of the spool being greatest at the beginning of the winding operation, and being gradually decreased as the winding is continued and the bulk of the film on the spool increases, thereby maintaining a substantially uniform tensional strain

on the film throughout the entire winding operation. Nick Power, 115, Nassau Street, New York, U.S.A., and Benjamin Morton, 253, Broadway, New York, U.S.A.

**SELF-MOUNTING PAPER.**—No. 25,922, 1905. The inventor proposes to coat paper (before sensitising) with shellac or other waterproof substance which is softened by heat. The finished prints are then mounted by passing a hot iron over prints, card mount, or by otherwise subjecting them to heat. Reference is made by the Comptroller to the specification of Denon Frères, No. 17,471, 1901. Warwick Brookes, of 350, Oxford Road, Manchester.

**COLOUR PHOTOGRAPHY.**—No. 9,100, 1906. The invention is a modification of the starch grain process of colour photography already the subject of Letters Patent (specifications 122,988 and 25,718, 1904). In place of filling the interstices of the coating of starch grains with black powder (e.g., charcoal), the inventors now subject the coating to rolling. The process is as follows:—After having spread on the transpa-

Fig. 1.

support, which may be glass, film, paper, etc., a layer of pitchy material, there is spread by the means already described in the above mentioned specifications a layer as uniform as possible of coloured particles, in which layer the grains touch each other without being superposed on each other, as shown at Fig. 1. These grains, composed of fucula, starch, or of analogous matter, are then brought to a suitable hygrometric

Fig. 2.

condition in order to acquire the necessary plasticity for the next operation. In this state the coloured coating is submitted at the same time as its support to a direct pressure or to rolling which crushes the suitably softened coloured grains and causes them to fill the spaces so as to form, as shown in Fig. 2, a mosaic covering the support at all parts. This method has, over that of filling with black powder, the advantage of

Fig. 3.

producing more luminous plates, and of regularising the thickness of the coating in such manner as to avoid as much as possible the diffusion of light. The coloured coating thus obtained is, as before, covered with a transparent varnish above which is spread the sensitive coating. B. J. B. Mills, for La Société Anonyme des Plaques et Papiers Photographiques A. Lumière et ses Fils, 21, Rue St. Victor, Lyons-Monplaisir.

**MASKS.**—No. 5,670, 1906. The invention relates to the printing of border negatives, in which the part having the border mask and the picture opening, and that having the picture mas-

and the border negative are made in one piece of material, folded upon itself, or are connected together in any suitable manner, and a gummed strip is provided to secure the picture negative over the mask, so that the negative always occupies exactly the same position with regard to the picture opening. Also all the parts may be secured in book-form, and a piece of material, such as gauze, wood veneer, or canvas, may be provided for the purpose of printing on the sensitised surface an attractive background. As shown in Fig. 3, the bottom sheet *a* is constituted by gauze, or it may be canvas, wood veneer, or the like, and over it is placed a sheet *b*, which represents the border negative and picture mask. On top of this is placed the border mask *c*, having the picture opening. Attached to the border mask *c* is a strip of suitable material *d*, provided with gum or other adhesive substance to which the negative or film *e* is secured. In use, the sensitised paper or the like is placed between the flaps *c* and *b*, which may be separate and connected together as shown in Fig. 3, or these two may be made of one piece of material folded upon itself. The gauze or other sheet *a* may be used or not, as it can be readily folded over or under the sensitised paper. The border negative is preferably first printed from, during which time the part to be occupied by the picture is protected by the mask *b*<sup>1</sup>, and after this printing is finished, the sensitised sheet is removed and reversed, so that the printed portion is now covered by the solid part of the border mask *c*, while the part that was covered by the mask *b*<sup>1</sup> is opposite the picture opening *c*<sup>1</sup> in the part *c*. The picture negative *e* is then over the mask *c*, and the arrangement is exposed as shown in Fig. 1 for printing the picture proper. It is to be understood that the applicants do not hereby suggest that the use of a border negative with a picture mask and a border mask with a picture opening, or of a background pattern or negative, is broadly new, or that the conjoint use of two or more of these devices is broadly new. Leipziger Buchbinderei Actien Gesellschaft vorm Gustav Fritzsche, Crusius Strasse 4-6, Leipsic, Germany.

#### FORTHCOMING EXHIBITIONS.

September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.  
 September 20 to October 27: Royal Photographic Society.—Sec., J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.  
 October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.  
 October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.  
 Rotherham Photographic Society.—Annual exhibition. "Open."  
 October 17 to 20. Entries close October 8; exhibits, October 13.  
 November 15 to 17: Burnley Camera Club. Entries close November 10. Sec., Fred Whitaker, Mechanic's Institution, Burnley.  
 November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismire," Stafford Road, Southsea.  
 November 20: Sefton Park Photographic Society.—Sec., A. W. Parr, 34, Loudon Grove, Liverpool, S.  
 November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.  
 December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Kimber, "Oakdens," Highfield, Southampton.

1907.

February: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.  
 February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.  
 February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.  
 March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.  
 April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.  
 October 24 to November 14.—West of England Exhibition (Photographic) Section. Entries close October 1. Sec., A. D. Breeze, 41, Union Street, Plymouth.

## New Books.

MESSRS. CASSELL AND Co. have issued, as a volume of their "Work" series, a handbook on "Photographic Chemistry," a digest, so it is admitted in the editorial preface of Mr. P. N. Hasluck, of articles "scattered over the columns of 'Work.'" It is scarcely to be expected that this digestive process can produce anything very admirable as a text book on one of the most difficult subjects to which a writer may apply his pen. As a result, we find the contents very miscellaneous in character, scraps of chemical theory being sandwiched between thick slices of text dealing with laboratory practice, such as distilling water and bending glass tubes. We cannot accuse the unknown author of gross misstatements, but the book is a tangle of facts jumbled together and overloaded with irrelevant matter to such an extent as to be of little use to the photographer who wishes to learn something of the chemistry of his subject.

## New Apparatus, &c.

The "Hana" Bromide Printing Machine. Made by Houghtons, Ltd., 88, 89, High Holborn, London, W.C.

The demand for photographic picture postcards having given an impetus to the supply of mechanical aids to the rapid production of bromide and gaslight cards, every new piece of such apparatus should be eagerly examined by professional photographers, as a new accessory to profit-earning in this now active branch of the

Fig. 1.

photographic business. It is one great recommendation to the "Hana" machine that its design was undertaken, and the first working instrument made by Mr. Hana, the theatrical photographer, of Bedford Street, Strand, for his own use in postcard production, and the appearance of the machine on the market has not taken place until some months' constant use had proved the ability of the machine to answer the requirements for the rapid exposure of development papers.

Among the good points of the machine, from a practical point of view, we signalise the following as of primary importance for rapid work:—

The negative is changed and fixed firmly in position in a few seconds.

In feeding sensitive paper or cards to the machine, each piece is placed instantly into exact register, a large edition of prints being uniformly identical.

These, as we have said, are the two chief qualifications for rapid work. The reader will gather from them and from the illustrations that the "Hana" is a hand-fed machine—the type of bromide printer which is proving itself the most capable of responding to every-day work, for the reason that it is free from complicated mechanism, that every operation is under inspection, and that changes in the brand of printing material, in the portion of the negative to be utilised or in other respects, can be instantly recognised as necessary, and as quickly made.

As will be seen from the drawings, the "printing frame" portion of the machine is the face of the wooden chamber (Fig. 1), having a door on the right. This face is glazed, and the negative is held firmly against it by the hinged frame immediately below the pressure back. The negative—which may be whole-plate or the very smallest—is centred over the opening, and on being fixed by a turn of a lever below the frame will give print after print exactly corresponding to the opening of the cut-out.

In making each print the paper or postcard is placed against two stops, and pressure applied to the footboard with the heel. This movement closes the back against the paper, and lowers the ruby window separating the light. To arrest exposure, the heel pressure is released, and the other end of the footboard pressed down with the toe, cutting off the light and opening the back. This series of exposures goes on as fast as the papers can be fed in, both hands being at liberty for handling the cards, and the exposures being controlled entirely by the foot. The chamber

Fig. 2.

between the negative and the light is grooved to receive ground glass or opal when working with rapid bromide papers, and for the reception of a vignetting plate, which is provided with a large aperture, over which a suitably pierced card is held by a couple of springs, being adjusted to the negative while the effect to be obtained is in sight. On our paying a visit to his studio, Mr. Hana himself showed us the delicacy of the vignettes obtained in this way, and at the same time allowed us to see the machine doing

its daily work in a way which entirely confirms us in what have written of it.

We have written much, and yet not more, we feel, than a workmanlike and strongly-made piece of apparatus deserves. It is pre-eminently fitted for its work, is capable of giving with rapidity prints which lack nothing as regards sharpness and

Fig. 3.

response with that part of the negative selected. The machine as now issued makes prints up to half-plate size, but will take negatives up to whole plate. The lantern portion is provided with a ruby and orange window on either side, affording a safe light for development of plates and papers. The complete apparatus costs £4 15s., complete with incandescent burner, and can be supplied also for oil or electric light.

The "Primus" Postcard Registering Frame. Sold by Messrs. W. Butcher and Sons, Farringdon Avenue, London, E.C.

In this very simple yet efficient accessory Messrs. Butcher have provided the means of taking postcards from a negative without loss of time in placing each card in position. The frame is fixed to any ordinary half-plate printing frame by the set screw at each end

and the cards are then dropped into the framework and exposed without loss of time in adjustment. For gaslight printing, pressure of the hand on the spring-back of the registering frame is sufficient. For printing-out papers the springs of the printing frame are employed. In either case the back of the registering frame springs up on pressure being released. The frame is strongly made, and costs 4s. 6d.

## New Materials.

Kodak "Velvet" Papers. Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

Messrs. Kodak, Ltd., have introduced, under the above title, a new surface of paper in three of the leading and well known printing materials manufactured by them—viz., Solio (print-out), Dekko (gaslight), and bromide. The surface effect is almost identical in each case, and falls between a glossy and a matt, a happy compromise, which should be acceptable to both amateur and professional photographers. The amount of gloss is difficult to describe, but it roughly resembles that of a carbon print, as that term is usually understood. A carbon print, we know, may have any surface whatever, but the peculiar lustrous, yet not glossy, surface, which is familiarly described as "carbon," fairly represents the effect obtainable with the new Kodak "Velvet" papers. Of the three, the prints obtained on the Solio paper strike us as the most uncommon, and likely to be regarded by a photographer's customers as something out of the ordinary. The bromide and gaslight prints more closely resemble those of cold tone obtained on some brands of collodio-chloride paper, and it is no disrespect to the papers or to the emulsions they bear to describe them in this way. We would add that the new "Velvet" papers are manufactured in all the usual sizes, and are supplied at the same prices at which the several brands of paper are sold.

In order to give the amateur worker, wherever he may be, and however slender his resources, an opportunity of making a test of their P.O.P., Messrs. John J. Griffin and Sons, Ltd., Kingsway, London, W.C., are offering a sample outfit, consisting of six 4-plate pieces of glossy "Special" P.O.P., the same quantity of the matt paper, and one packet of "Tonix," the combined toning and fixing bath. The materials are sent post free on receipt of sixpence, and the outfit may be obtained from the leading dealers.

## Commercial & Legal Intelligence.

INDECENT Photographs.—At the Marlborough Street Police Court on Thursday, Edmund Dusedau, 31, a postcard publisher, of German nationality, of Plaistow, was charged on remand with selling four improper photographs to Detective-Sergeant Smith. The transaction took place in Upper Marylebone Street, W., about a week ago, and the prisoner was at once arrested. Sergeant Smith said that the accused had been previously convicted on three occasions, when thousands of cards were destroyed. Mr. Walter H. Cowl, solicitor, who appeared for the defence, urged that the transaction was an isolated one, and that the prisoner had now given up selling these cards. Mr. Kennedy said the prisoner carried on this corrupting business in spite of warnings. He would have to go to prison for a month and be recommended at the expiration of his sentence for deportation. Eighty of the cards would be destroyed.

An application was made for the discharge of George Wm. Austin, photographer, 15, Highbury Place, Islington, N., at the London Bankruptcy Court on August 9, before Mr. Registrar Giffard. Under the circumstances the Official Receiver reported that the debtor had committed the following offences under the Act: That the debtor's assets were not a value equal to a dividend of 10s. in the £, on the amount of the unsecured liabilities; that the bankrupt had omitted to keep such books of accounts as were usual and proper in the business carried on by him, and as sufficiently disclosed his business transactions and financial position during the three years immediately preceding the date of the receiving order. The Registrar, in giving his decision, said if the liabilities had been larger he might have suspended the discharge for more than two years, because of the debtor's carelessness respecting his book-keeping, but the

deficiency only amounted to about £400, and he should therefore order the discharge to be suspended for the minimum period of two years.

THE first meeting of the creditors interested under the failure of Ellen Jacklett, of Victoria Road, Aldershot, trading as J. W. Jacklett, photographer, took place last week. The statement of affairs disclosed gross liabilities amounting to £734 19s. 10d., of which £655 15s. 3d. was due to unsecured creditors. The assets were estimated to produce £116 6s. 4d., from which £79 4s. 7d. had to be deducted for the claims of preferential creditors, payable in full, leaving the net assets at £37 1s. 9d., and disclosing a deficiency of £618 13s. The debtor alleged her failure to have been caused through bad trade at Bexhill, and illness of herself during 1902 and 1903. The receiving order was made on her own petition, and she had since been adjudicated bankrupt. In the year 1894, on the death of her husband, she took over the business, which he had carried on up to that time at Aldershot as a photographer, and she carried on that business at the date of the receiving order. In or about January, 1903, she took over a photographic business at 7, Sea Road, Bexhill, which was carried on under the management of her son, but this business was closed in April, 1905. She made a loss in connection with this business between July, 1904, and April, 1905, of £296. The only book of account she had kept was a day-book. She had not taken steps to ascertain her financial position during the past three years. She was insolvent to the extent of £374 in July, 1904, but she did not become aware of the fact that she was in a state of insolvency until April, 1905, when she closed the Bexhill business. She admitted that she had contracted debts since April, 1905, which were now owing, with most of her present creditors. Of the unsecured creditors' claims, £42 was in respect of money lent, and the balance was due in respect of goods supplied and work done. Eventually the estate was left in the hands of the Official Receiver for summary administration in the usual manner.

W. H. HARRISON, LTD.—Capital £5,000, in £1 shares (2,500 preference). Objects: To acquire the business carried on by W. H. Harrison, of 7, Onslow Place, South Kensington, S.W., and to carry on the business of photographers, photographic artists, makers of scientific, photographic, and surgical instruments, etc. No initial public issue. Registered office, 4, Onslow Place, South Kensington, S.W.

THE Affairs of Mr. Van der Weyde.—Van der Weyde (Henry), photographer, 182, Regent Street, W., at the London Bankruptcy Court, on August 7. This bankrupt renewed his application to Mr. Registrar Linklater for his order of discharge. Mr. Walter Boyce attended as Assistant Receiver, and the applicant was represented by Mr. Hansell. According to the Assistant Receiver's report, the liabilities were estimated by the bankrupt at £12,627 13s. 9d., in respect of which proof of debt, amounting to £29,582 15s. 7d., had already been admitted by the trustee. The assets had realised £163 14s. 4d., and a first and final dividend of 1gd. in the £1 had been paid. The bankrupt attributed his failure to loss on trading and to inability to realise his inventions. The Assistant Receiver opposed the application, on the grounds that the bankrupt's assets were not of a value equal to 10s. in the £; that he had continued to trade after knowing himself to be insolvent; that he had contributed to his bankruptcy by rash and hazardous speculation and culpable neglect of his business; and that he had on a previous occasion made an arrangement with his creditors. The case had been adjourned to give the bankrupt an opportunity of making a reasonable offer to secure a sum to pay a dividend of 5s. in the £ on the amount of his liabilities. Mr. Hansell now stated that it had been found impossible to find sufficient security; up to the present the bankrupt's inventions had not resulted in anything substantial for the creditors, and, in all the circumstances, the case would have to be dealt with on its merits. His Honour suspended the order of discharge for two years.

THE Burnley Camera Club Exhibition this year will be from November 15 to 17. It will be opened by the Lord Bishop of Burnley, and Sir John O. S. Thursby, Bart., will occupy the chair.

## News and Notes.

**NEW Eastman Factories at Rochester.**—To provide a home for the manufacture of Graflex, Folmer and Schwing, and other high-class cameras, new factories have been erected at Rochester in Caledonia Avenue. The factory is specially devoted to apparatus for the professional photographer. Among other cameras made here are the Cirkut panoramic cameras. The Cirkut camera takes pictures 16ft. or more in length. The camera is mounted upon a revolving base which moves in a circle mechanically in unison with the unfolding of the long film negative, so that a section of the entire horizon may be swept by the pressure of a bulb. Some remarkable panoramic views have thus been taken. One of these is a view of the San Francisco fire, taken from the top of one of the hotels as the fire swept toward the photographer. What is said to be the largest photograph in the world was taken with a Cirkut camera. The photograph is a panoramic view of the city of Washington representing nearly a complete circle of view—about 350deg. It is more than 19ft. in length. Photographs of large size (writes the "Rochester Post") have been made by enlargement processes and by making a number of negatives and printing them on one piece of paper, but this is a single negative made at one exposure. To print this great photograph required a printing frame 20ft. in length. One thousand ounces of developer were necessary for making one print. The photograph was taken by E. W. Brehm, of Rochester.

**The Exhibition Picture** (from "The Photographer").—I printed it on bromide, coarse, which gave no definition; In fiendish glee despatched it to a tip-top exhibition; To my surprise it gained a prize; success at last was mine; The picture was accepted, and they hung it on the line. Then everybody praised it; 'twas the picture of the year; The critics wagged their heads and spoke of breadth and atmosphere; I felt a trifle mean to think how cheap was my renown, For I never told the management they'd hung it upside down.

**A PROGRAMME** of lectures on "Nature" subjects for the coming season reaches us from Mr. Martin-Duncan, of whose truly marvellous photography we have had reason to speak during the past few years. Mr. Duncan's lectures constitute such a happy combination of information and entertainment that a society may consider itself fortunate in arranging for one in its programme. In these days it is not easy to find a subject to talk about interestingly, and Mr. Duncan is to be congratulated on having found subjects close at hand of which he has obtained series of photographs quite sensational in their realism. Mr. Duncan should be addressed at 3A, Bradley Gardens, West Ealing, W.

**"HOUGHTONS' QUARTERLY."**—We may state, in further reference to our recent notice, that the object of this quarterly is to supplement the local dealers' catalogues, and our readers are asked to apply for particulars to their local dealers direct. Messrs. Houghtons are prepared to send a copy regularly to any amateur who would like to have it, and who at the same time sends them his dealer's name and address.

Mr. J. HUBERT writes us as follows:—"Having worked up an additional connection as a portrait painter, black and white artist, and retoucher, in Liverpool and Southport, I find it interferes somewhat with the business I have been conducting for so many years at 138, High Road, Chiswick, W., as, although I have informed some customers, whose work I personally attend to, others still send their negatives and copies intended for paintings, etc., to London. Will you therefore allow me to say that for the rest of the season, until the end of September, negatives and enlargements intended for paintings and retouching should be sent to my Liverpool address, 10, Bold Place. On account of the excellent postal arrangements my clientele in London and elsewhere will find no delay in the despatch of their esteemed orders."

**THE** late Mr. James G. Murray, A.R.E.—Artistic circles in Glasgow have sustained a great loss by the death of Mr. J. G. Murray, which took place at Cambuskenneth last week. Mr.

Murray was a native of Aberdeen, and began life in the "Press" office there. Having a taste for art, he went to Mr. Wilson, the well-known photographers, where he acted as "touch" and also did lithographic work. In 1886 he removed to Glasgow and after some years' service in Messrs. Maclure and Macdonald he joined Mr. R. Clouston Young in an artistic and design business, working principally for the lithographic trade.

We regret to record the death of Colonel J. Gale, one of the most pictorial workers, a member of the Linked Ring since its formation, and an Honorary Fellow of the Royal Photographic Society. Colonel Gale's name will long be remembered in connection with that particular type of pictorial photography which has no parallel in the present wave of impressionism, is thoroughly good photography, and relies for its qualities upon its admirable presentation of natural scenes.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—There are approximately ten thousand professional photographers in business for themselves in Great Britain. About five hundred and fifty—that is to say, about one out of nineteen—of them subscribe to the Professional Photographers' Association. Someone complains that the Professional Photographers' Association is "not doing what was expected of it." Does he mean what the five hundred and fifty expected of it, or what the other nine thousand four and fifty expected of it?

NEMO.

To the Editors.

Gentlemen,—With reference to "Disgusted Assistant" and "Disgusted Employer," there is cause for complaint, I think, on both sides. May I suggest, first, that there are many assistants who do not understand the meaning of efficiency? These young men will not as soon apply for a place of operator as printer. Now, having worked for some twenty years at photographic printing, I find that there is much to be constantly learned, and that because one does P.O. printing under favourable circumstances, one is not a printer in the right sense of the word. There is working under all sorts of conditions—variation of temperature, different waters from different supplies, various brands of paper, methods of toning, methods of conditions of printing, sizes of work, various classes of negatives, etc., all of which require time to attain, as well as tact. Then we have the "hundred and one" different printing processes, all of which require special experience. Is it likely that a young man or woman who can only have had, say, four or five summers' or winters' experience, and want a situation, can be expected to show efficiency? The P.P.A. does its best, but it cannot possibly be expected to look into each individual case.

Then the "Disgusted Employer" side of the question is that he wants a staff cheap. He takes some four girls and a young man to do his work, and, of course, cries out about their non-efficiency and carelessness. First, his four girls have come to him because he pays them. No doubt they eventually expect to get married, and are not going to centre all their interest on his work. I for one should not expect it, having seen a good deal of the young woman element in photography, and I find that, unless under a good (self-respecting) foreman, they will not improve the quality of the firm's work. Now, gentlemen, I would suggest that "A Disgusted Employer" get an experienced working foreman, who will, by management of time and material, save the expenses of three such girls as are employed by him. A word to the wise is generally sufficient.—Apologising for intruding on your space, I remain, Sirs, respectfully,

F. G. W.

## Answers to Correspondents.

*All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d., each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

Smith, 35, New Road, Grays, Essex. *Two Photographs of Grays Beach.*

E. Fritch, 25, Russell Terrace, Leamington Spa. *Photograph of entrance to Eton College Chapel, with the Rev. Dr. Ware posing to Mr. J. S. Sargent, R.A.*

Shackleton, 9, Cross Street, Abergavenny. *Photograph of Clydach Falls, Abergavenny.*

A. Baker, 113, London Road, Southborough, Kent. *Photograph of the exterior of Hotel "Ye George and Dragon," Speldhurst.*

H. Dee, 310, King's Road, Reading, Berkshire. *Photograph of the Reading Football Club, Ltd., 1906-7.*

Allison, 42, Scotch Street, Armagh. *Photograph of Memorial Statue to the Royal Irish Fusiliers erected on the Mall, Armagh.*

**EXAMINATIONS FOR PROFESSIONALS.**—I am anxious to know what books are published on photography for professionals, and also to get information about examinations in photography. I am at present a general assistant in retouching, mounting, spotting, etc., but have had no experience so far in operating, printing (silver prints excepted), and developing, and really know less about those branches than the ordinary amateur. It is my intention to take a studio in the future, and, of course, I want to be prepared for it. I have worked with two photographers, and neither of them has been willing to teach me anything in this way, even by taking a lower salary, and if I can obtain the necessary knowledge from books, and the use of a camera of my own, I shall be glad to know. I fear, perhaps, this may be too lengthy a question to answer in your paper, but perhaps you could mention someone who would give me the necessary information.—F. A.

You had better get the two volumes of "Professional Photography," by C. H. Hewitt, and write to the Photographic School, Regent Street Polytechnic, for prospectus of the classes.

**PROTECTION OF COPYRIGHT.**—About four years ago I was asked to photograph the abbot of a monastery near here, but on the understanding that he paid me for the negative which I de-

livered to him, the lay brothers doing the prints. The copyright, of course, was his. Now he is dead, and I wish to know if I can legally reproduce his portrait for sale, as it is unlikely that he has assigned the copyright, if ever it was registered.—OTHELLO.

The duration of the copyright has nothing to do with the ownership. It is determined by the author—i.e., it lasts for his lifetime and until seven years after his death. It will not have lapsed until you have been in your grave seven years.

**POSTCARDS.**—I see reference made in the "Journal" to some process of doing postcards while you wait. Could you give any particulars of such?—P. D.

As you do not give a reference, we are in doubt as to what you refer to. Probably the method involves the use of gaslight or bromide papers printed with one of the rapid machines, such as the "Hana," described this week.

**STAINS ON P.O.P.**—I enclose herewith two prints on P.O.P. by different makers. Could you tell me through your valuable paper the cause of the stains? They appeared just previous to toning. The first half of batch toned all right except one, and the others are all more or less this way, and refuse to tone even. As far as I can gather from inquiries it was impossible for anything to get into the washing water, and the dishes are used only for washing P.O.P. prints. The hypo being mixed previously by another assistant for fear of contaminated hands. I have had this occur four times recently, and it is very serious. My private opinion is that it is hypo in the washing water, though the printers say this is quite impossible. As about 100 prints are spoilt this time, it could hardly be a drop from an improperly washed enlargement, the only thing in the room at the time, and at the other end of large sink. Both assistants in this case are experienced and careful workers, and did not go near each other. After stains were first noticed the prints were immediately all re-washed, but it was too late, as they still refused to tone. It is not fault in paper. It is not fault in printing-room, or some of first batch would be spoilt. Ordinary washing and separate toning bath used.—"TRADER."

As far as we can judge, only hypo or other chemical (e.g., sulphite of soda, acids, etc.), can be the cause of the stains. Very moderate traces would be sufficient. We should say if you compel your printers to take precautions as to the purity of the wash water there will not be a repetition of the stains.

**COUPON BUSINESS.**—(1) Trade has been so quiet this spring that I think it is desirable to take some steps to revive things. I have read the various American articles on this subject in the JOURNAL, and have thought the coupon system might suit my purpose, although I have no particulars or very clear ideas of the said system. Do you think it is against the dignity of the photographic business, or the reaction unfavourable? I presume it means that you must run a cheap line, say, a dozen cabinet panels, perhaps printed in bromide, for 10s. 6d. My best line at the present is one dozen Aristo platino panels, carefully produced (good work, etc.), for 21s., in two positions. I should scarcely know what to say on a circular or how to word the coupons. I should be glad of your opinion and any details that would help. (2) What is the best method of writing titles on negative for postcard work? The best I can do is to reduce some part of foreground with dry pumicestone (fine), and write the letters backwards, with a pen and ink; but this is far from satisfactory.—COUPON.

One objection to the coupon business is that it is so closely associated with the methods of fraudulent parties, whose success in selling worthless coupons by house to house canvassing, are constantly being reported in the JOURNAL. If you consider the plan advisable—it usually succeeds best in districts of the cheaper class, such as shop assistants, mechanics, and small shopkeepers—we see no reason why you should not make it dignified, say, by having it to come into force on the occasion of some event in your own town, and arranging to close it at the end of a certain period. If you are, as you ought to be, a member of the P.A.P., and addressed the secretary, he would doubtless be able to put you in communication with some member who

would let you have a circular from which to work. (2) With the "Nameit" type outfit from your dealer, or by setting up the titles in large size, from type or with a rubber letter outfit, photographing a number together, and stripping each title on to its negative. The latter method is used by the postcard printers.

J. S.—Add enough 10 per cent. solution of potass ferricyanide to 4oz. per pint solution of hypo, to give a yellow solution. If too slow in action, add more ferricyanide.

STRENGTHENING BELLOWS OF CAMERA.—I have a 15 by 12 camera, the bellows of which are in good order at the sides, but the bottom has become limp, and will not keep in shape. Can you advise what should be done with it to stiffen it, so that it will hold in shape?—GEO. FRANK.

The only suggestion we can make is that you strengthen the gussets of the bellows by glueing strips of thin cardboard on the inside, and then blackening them over. If this does not give sufficient rigidity, you might put further strips on the outside.

PHOTOGRAPHING INTERIOR.—I have to photograph the interior of a large church by flashlight, and I shall be very grateful if you will kindly give me your valuable help. It is quite impossible to take it by daylight, as the spreading of the light from the east window (which is of clear glass) entirely obliterates the rest of the picture. I shall therefore be glad if you will advise me, although I am afraid I cannot give you much definite information as to the size of the building. But I imagine it capable of seating about 1,000 people. Would you therefore be good enough to tell me whether flashaxe candles would give sufficient illumination, or whether I had better use magnesium ribbon or powder, and, if so, what quantity?—M. D.

The "flashaxe" candles are very good for lighting interiors, but they must be placed so that they are not seen by the lens, and be fired simultaneously. We can give no idea as to the light that would be required without fuller particulars as to the size of the church, and its form, or even without seeing it. We think you would be far more successful by working by daylight. Cannot the light from the east window be subdued by placing a light sail cloth outside; or a dark tarpaulin might be used, and removed before the exposure is quite completed. This would be better than using artificial light.

COPYRIGHT.—We should be obliged if you would kindly let us know what steps we can take re the following. A publishing house or firm has placed on the market small negatives one inch square (reproduction of our local views) without our knowledge. As there is no name or address on their packet (containing negative and a small piece of P.O.P.), we have made inquiries of the shopkeepers where they are sold, and they say they do not know the firm's name supplying them. What we should like to know, can we take any action in the matter, seeing that the views are not copyright; and, if we can, how should we proceed? And if not, can we do so if we were to copyright?—W. C. CURNICK.

We should advise you to register half a dozen subjects, and then take steps to prove the sale of these subjects by the actual producers or their wholesale agents. Even the local shopkeeper has no right to sell the reproductions. You will find all the information on registration in the "Almanac."

GELATINE RELIEFS.—I should esteem it a favour if you could give me any idea as to where I can obtain a formula for making a bichromised gelatine solution, used in the swelled gelatine process.—EDDIE J. DUXFIELD.

The following may be used:—Nelson's No. 1 sheet gelatine, 2oz.; water, 7oz.; bichromate of potash, 90grs. As the film must be thick, unless you have the means of drying it quickly, there is the possibility of its becoming insoluble before it is dry. The most convenient way of working the swelled gelatine process is to form the film first and sensitise it afterwards. Sheets of gelatine suitable for the purpose are sold by most of those who supply lithographic materials. We

have had it from Cornelissen, Great Queen Street, W.C. soaked in a 3½ per cent. solution of bichromate of potash just flaccid, and then hung up to dry.

DAGUERREOTYPES.—(1) I should be much obliged if you would kindly give me some hints on copying an old daguerreotype want to avoid, if possible, taking the glass off; but the reflections are very troublesome. (2) Will you also kindly me a formula for gold-toning P.O.P. with soda formula J. S. M. W.

(1) We published an article on the subject in BRITISH JOURNAL of Dec. 1 last. There is no risk in removing the picture from its case, as the covering glass is simply bound to it with paper as a rule. To photograph, place the picture near the window, and at right angles to it, aiming at strong side light which is necessary to prevent reflection of surrounding objects entering the lens. The surface of daguerreotype plate is extremely delicate, and should on account be touched with the fingers. (2) Gold chloride, 1 sodium bicarbonate, 2grs.; formate, 8grs.; water, 20ozs. Immerse the prints in a 10 per cent. solution of salt before entering the bath.

CANVASSER.—Your present employer can certainly discharge you the spot if you do as you suggest, and you will thoroughly deserve it. Your moral sense appears to be defective or existent.

G. C. P.—The lens, we should say, suffers from flare, and strong light would give the patch of fog on the negative.

D. GIRDLESTONE AND OTHERS.—In our next.

THE Royal Photographic Society of Vienna.—By an act of Emperor of Austria on June 29 the title "Kaiserliche-Königliche" which corresponds with the designation "Royal" in this country has been conferred on the Photographic Society of Vienna, an honour, which is not a common one, should gratify the many stalwart supporters of the society, of whom some doubtless recall its establishment forty-six years ago. To none, however, should afford greater pleasure than to the present president, Dr. J. Eder.

THE late Mr. S. Poole.—The death is announced of Mr. S. Poole, one of the oldest inhabitants of Teignmouth. Until ten years ago Mr. Poole carried on the business of photographer now in the hands of his son.

MR. R. FELLOWS WILSON has moved from his studio in Bedford Gardens to No. 4, Sloane Street, W.

MR. E. J. THOM, late of 9, Giltspur Street, advises us of removal to more central premises at 63, St. Paul's Churchyard, London, E.C., where all communications as to his lines of paper mounts, backgrounds, etc., should be addressed.

In reference to our note of August 3 on Mr. Watmough's engagement with Messrs. T. Illingworth and Co. as demonstrator, we asked to state that Mr. Watmough will represent his firm in London and district, the provinces being in the hands, as hitherto, of Mr. F. J. Stedman.

\*\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

## SUMMARY.

M. Leon Vidal, we regret to say, died suddenly at his country seat, three weeks ago (P. 672.)

Copyright in sculpture. The rights of photographers, as instanced in a case mentioned by an Irish firm of photographers, should be noted by others. (P. 678.)

A question of copyright law, the marking of photographs as "copyright," is discussed in reference to two recent instances. (P. 663.)

In some notes on the three-colour prints, now to be seen at the Earl's Court Exhibition, Mr. F. C. Tilney makes a strong claim for the Continental worker. (P. 664.)

A French worker's apparatus for ascertaining the ratios required by three-colour filters and the intensity of three-colour inks is described on page 667.

Telephoto lenses, methods of colour photography, and cinematographs are among the patents of the week. (P. 673.)

A review of the portraiture of G. F. Watts, by Mr. A. V. Kenah, should encourage photographers to make a more serious study of art principles and of their application to individuality in portraiture. (P. 665.)

A recent Parliamentary report raises an alarm as to the danger to paintings—and therefore to photographs—from the increased proportion of sulphur compounds in coal gas. We recommend a method of framing, which in any case is one which may be adopted. (P. 662.)

A correspondent in Siam communicates his remedy for yellow stained negatives. (P. 678.)

Dr. Lindsay Johnson has published a new method of estimating the focal length of a lens, apropos of which attention may be called to the loose sense in which the term "infinite distance" is sometimes used. (P. 660.)

In improvising temporary lens-panels and similar accessories, the "three-ply" fret-wood is an extremely useful material. (P. 662.)

A camera specially designed for photographing fossils has been made for the United States Geological Survey. (P. 672.)

## EX CATHEDRA

### The Measurement of Focal Lengths.

In "The Photographic Journal" for August, Dr. Lindsay Johnson gives a method of determining focal length that may possibly be of considerable service

He points out that if we focus on two objects at an infinite distance, adjusting the camera so that one of the two images falls on the lens axis, then the distance between the two images is equal to the focal length, if the objects subtend an angle at the lens of 45 deg. If the objects subtend an angle of 18 deg. 26 min., or one of 26 deg. 34 min., then the separation of the two images is either one-third or one-half the focal length. If no objects subtending these angles are to be found, the angle between two convenient objects can be measured; the tangent of that angle is then a constant by which the distance between the two images can be divided to find the true focal length. Opticians who deal in both photographic lenses and theodolites or sextants will have no difficulty in fixing upon two suitable distant objects, but the ordinary photographer may have some trouble. We may suggest that a simple method of fixing the objects would be to sight one object over the points of two vertical needles, fixed points up in a drawing board, and then place a third needle in alignment with the second object and the rearmost needle. The angle included by the three needles could then be measured with a protractor. As an alternative, the procedure could be reversed, and the three needles set up at some definite convenient angle and two suitable objects found to fit them. It is, however, not absolutely necessary that the objects should be at an infinite distance. If sharp focus is first secured on infinity and the lens is then stopped down so as to secure plenty of depth, two near objects could be employed, and with a very short focus lens the objects and the camera might all be contained within the limits of a large room. To ensure accuracy, the lens would have to be placed so that its front node would come very approximately over the apex point of the angle subtended by the objects; also, it would be necessary to be sure that the focal length did not vary with the aperture.

### What is Infinity?

In describing his method of measuring focal length, Dr. Lindsay Johnson defines "infinity" as "any distance greater than six hundred times the focal length of the lens." The expression "infinite distance" is used in a very lax fashion by photographers generally, and there is a very common impression that any object beyond a certain number of focal lengths may be considered to be at an infinite distance. We have seen one hundred focal lengths given as the minimum distance, but while Dr. Lindsay Johnson's six hundred focal lengths is a better approximation, we

must point out that all such rules are founded on a misapprehension. An object may be considered to be approximately at infinity when its image is approximately in the principal focal plane of the lens, and if we calculate the displacement of the image from the principal focal plane, we find that under Dr. Lindsay Johnson's rule the errors for 3 in., 6 in., 12 in., 18 in., and 24 in. lenses respectively are .005, .01, .02, .03, .04 inches. An image that is one twenty-fifth of an inch out of place cannot be considered to be approximately in the focal plane, though a displacement of one two-hundredths of an inch may be negligible. The rule, in fact, breaks down for lenses over 6 in. focal length if one-hundredth of an inch is considered to be the greatest allowable error. The correct method of arriving at a minimum distance of approximate infinity is to first decide on the maximum permissible displacement of the image, and then divide that amount into the square of the focal length. The result is the extra-focal distance of the nearest object that may be considered to be at an infinite distance. In a problem concerned only with placing the focussing screen as nearly as possible at the principal focus, the question of aperture does not properly come in, but it may be as well to note that under the correct rule the circle of confusion representing a point at true infinity is very approximately the same with all lenses working at the same ratio aperture. Under the incorrect rules, the circle increases as the focal length increases.

#### Fitting Lenses to Cameras.

We have found convenient when using lenses belonging to other cameras. It is easy, of course, to have a second flange and panel when using the lens upon a second camera, but apart from the expense, the plan is not the most advisable. It is more convenient and economical to have the lens flange screwed to the panel of the smallest camera, and, if it is wanted for another camera, to make another panel fitting the larger camera, and screw upon it strips of wood the thickness of the smaller panel, so as to make a shallow recess to receive the latter. Four turn-buttons will secure it in place, and the one recess will take any other lens that is used on the smaller camera. A similar panel with recess can be fitted to all cameras of a larger size, including studio, copying, or enlarging instruments. The panels are easily made by using "three-ply" wood, which consists of three thin pieces glued together, with the grain running in opposite directions, to prevent warping. It can be bought at shops where fretwork materials are sold. If "satin walnut" wood is chosen, the openings can be cut with a good sharp knife or with the washer-cutter recommended in a former number. This same two or three-ply wood will be found extremely useful to photographers, for carriers, and the thousand-and-one little jobs necessary when enlarging or reducing from odd-sized negatives, as it will not warp or twist. But if it is to be kept in a damp room it is well to put a few small screws through it, to prevent the wood coming apart through possible perishing of the glue.

#### Processes at the R.P.S. Exhibition.

In our correspondence column this week is a letter in which the writer suggests that the process by which the pictures to be shown at the coming exhibition will owe their existence should be mentioned in the catalogue. Until the last two or three years this used to be done, but it was discontinued, for the reason, if we are not mistaken, that the declaration of the process was thought to be a reflection, in some obscure way, upon the quality of the photograph

as a work of art. In the pictorial section it is the picture themselves that are of chief interest, and not the process by which they are made; but there is a technical side to photography as well as the artistic—the former is that the Society is supposed to foster, as well as the latter—and there seems no real reason why the process employed in making the pictures should not appear in the catalogue. A rose by any other name will smell sweet, and a picture will not have its artistic merit detracted from because it is a toned bromide instead of being a sepia platinum print. Like our correspondents, including experts, find it next to impossible to decide the difference between, say for example, a good platinum-matt bromide print and a platinotype, without making a chemical test, and it is equally difficult to distinguish a good sepia-toned bromide from a sepia carbon, or a sepia platinotype, particularly if they are similar colour and on a similar rough paper, and particularly when they are framed and hanging on the wall. There are at the present time so many different processes in vogue, all of which yield such excellent results, that the practice would certainly add to the interest with which the exhibition would be visited by all except a small minority. There is another point, also, in connection with the subject. Many of the pictures exhibited are for sale, and the purchasers interested in obtaining a permanent print will doubtless like to know the process employed in its production.

#### Choosing the Carbon Surface.

The carbon print, as everybody should know, may have any surface, from the coarsest of the coarsest drawing-paper to that of the highest glaze of an enamelled P.O.P. Yet the term "carbon surface" is nevertheless one which is understood to represent the texture of a carbon print as usually produced on the ordinary smooth single transfer paper, a texture, too, which is very well imitated in several commercial printing-out papers. To many, the semi-gloss of this surface is distasteful, and it may be useful to mention how it may be converted into a matt without the aid of a coarser transfer paper. If, when the print is taken out of the washing water, after aluminizing, it is squeezed on to a piece of matt opal glass, and allowed to dry upon it, it will be found when stripped off to have the matt surface of the glass. If, on the other hand, a more glossy surface is desired than that yielded in the ordinary way, the print should be squeezed on to a piece of plain glass, or a ferrotype plate, in the same way as P.O.P. prints are sometimes treated, and it will then have a similar glazed surface. Double transfer prints can have their surface modified in a similar manner. In this case, after the prints have been stripped from their flexible support, they should be allowed to soak in cold water for an hour or two, so that the gelatine is thoroughly softened, before they are squeezed upon the matt or plain glass, as the case may be.

#### Danger to Photographs.

In a memorandum which has been recently issued as a Parliamentary paper, Professor Church, who was engaged a year or two ago to restore and arrest the further decay of the frescoes in the Houses of Parliament, says that owing to the increased licence allowed to gas companies in the use of sulphuric acid, which is so deleterious to pictorial and other artistic productions, is now more prevalent in the atmosphere of London than ever before. This is very disquieting as regards valuable works of art, but it is, in anything, more so with reference to photographs, especially if they are by a silver process. Fumes from burning gas have always contained a certain amount of sulphuric

acid and other sulphur compounds, though we must admit that Professor Church's strictures come as a surprise to us. We await authoritative figures in proof of them before accepting them. Nevertheless, burnt coal gas remains, as it has always been, a lurking danger to silver pictures, the more especially when they are but ill-protected by frames, such as is the case with many bromide enlargements. Under these conditions, it is not at all surprising that, in a comparatively short time, signs of change—yellowing of the whites and sometimes bronzing in the shadows—are visible, although considerable care was supposed to have been taken in the production of the prints. Seeing the existing state of things, it behoves the conscientious photographer to see bromide enlargements supplied by him are secured air-tight in their frames—or as air-tight as possible. Too frequently, when a picture is framed, no heed is paid as to its future; it is simply laid in the frame, the backboard put in and secured with brads, and a paper backing put on. As a result of this perfunctory treatment, the mount in time becomes soiled with dust or smoke. Very obviously, where dust and smoke can gain access, injurious vapours will also penetrate, with still greater ease, and consequent deleterious action on the picture. The proper course is to adopt the plan by which picture framers secure valuable engravings entrusted to them. First, the glass is secured in the rabbet of the frame with strips of good quality paper stuck on with paste. Then the print is placed in, and on that a closely fitting backboard is secured with brads. A piece of stout brown paper is then damped, allowed to expand, and then fastened with glue to the back of the frame only—not to the backboard. When dry, the paper will be as "tight as a drum," and should at any time the backboard shrink, no fumes would get in. If precautions such as these were taken in the framing of bromide enlargements they would have a longer lease of life, even when they are hung in rooms where gas is burnt.

#### MARKING PHOTOGRAPHS "COPYRIGHT."

In our issue of August 10 there were two references to the marking of photographs with the word "Copyright" under circumstances when some doubt existed as to the proprietorship or registration of the copyright. In the first case, that of the portrait of Miss Marie Corelli, printed as a frontispiece to her latest work, "The Treasure of Heaven," our remarks were based upon the information given by Miss Corelli herself in connection with the fact that the imprint indicated that the photographer was proprietor of the copyright. It seemed reasonable to suppose that the copyright in the portrait was hers, since she went to the studio and was photographed in the ordinary course of business. It also seemed reasonable to assume that it had been registered by the photographer as his, rightly or wrongly, in the belief that he was justified in doing so. One would not suppose that a photographer would mark an unregistered photograph "Copyright." However, it is at the same time perfectly conceivable that on the termination of the secrecy which Miss Corelli was pleased to observe as to her identity, she may have assigned the copyright of the photograph to the photographer, or she may have made an assignment in which the copyright was held jointly by herself and the photographer. It may be useful if we assume that things were as first suggested above, namely, that the copyright was legally Miss Corelli's, and that the photographer had registered it as his property. We have thus a very good case upon which to discuss a point in copyright law

that is well worth consideration. In the case of an infringement of this particular copyright—the actual facts being those we have assumed—what would or what might happen? In a case at law nobody can say what will happen. If the photographer were to take proceedings he would certainly have no case, because he would have no locus standi—not being the owner of the copyright. If Miss Corelli were to take proceedings, her claim would be limited to that of the owner of an unregistered copyright—that is to say, she would have very little remedy. But what about the photographer? Clearly, he would have been guilty of an illegal action in registering a copyright that was not his, and also in marking as his copyright photographs which were not his copyright. The law assumes everyone to be acquainted with the law, and ignorance of the law is no defence. What would be his legal liability under the circumstances?

The second reference we have alluded to is the case stated by a correspondent, and briefly it is this: A person going to a photographer and paying for his sitting receives the prints marked "Copyright," or "Copyright registered." For the purposes of argument we may assume that in this case the wrongful marking of the photographs was intentional—that is to say, that an illegal act has been wilfully done. From a legal point, however, as we have explained, the position is exactly the same.

We have assumed that it is illegal for anyone other than the proprietor of a copyright to mark a photograph "copyright," but the Copyright Act does not specifically treat it as an offence. Therefore it would appear that it can only be dealt with under common law, unless the ingenuity of legal minds can show that the tenour of the Act inferentially provides for it. In the absence of a specific method of treating the delinquent, the only remedy can be the recovery of damages actually proved. We mentioned in an appendix to the letter of our correspondent that no case involving this point is recorded in the proceedings of the Courts, and under the circumstances this is no matter for astonishment.

With regard to patents, and the principle of patents is analogous to that of copyright, the similar condition is adequately provided for. The law protects the community from the assumption of patent rights by those not entitled to them. It goes so far as to make it illegal to mark any article as patent, even when patent has been applied for and before it is patented. Patent law is more comprehensive than copyright law, and it protects the patentee and also the community from frauds, which have their analogues in copyright, but against which there is no easy method of invoking the law owing to the primitive state of copyright law. Statute law is, however, but the basis of actual law. It is said that an Act of Parliament is not effective law until its provisions are confirmed by the final Court of Appeal—the House of Lords—and that is sufficiently near the truth to be accepted as fact. Whether it would be possible to establish effective means of preventing the unauthorised marking of photographs "Copyright," it is impossible to say, but it is undoubtedly highly desirable, in the interests of all, that there should be such means. Modern reproduction processes have given photography an importance commercially that was never dreamed of even a few years ago, and it is increasingly necessary, not only that owners of photographic copyrights should have ample protection for their property, but that the community should have similar protection from the fraudulent assumption of copyright.

Under our legal system, in a case of doubt, what the law is can only be ascertained by submitting a case to the decision of the judges, and the initiative must be taken by someone who stands to lose the whole costs

of the inquiry in the event of the judges not concurring in his view of the legal position. No one voluntarily takes the initiative in this way unless he be peculiarly litigious-minded, or unless his interests are such that the gain in the event of success is worth the risk of failure; but the injury done to any particular individual by the practice we are discussing cannot in the nature of things be very great, and hence it is that no one has considered

it worth while to take the responsibility of testing the law of the case. The injury is a small one to a member of the community, but to the community great, and the duty of dealing with it is a public rather than a private one. It would come well within the scope of the Professional Photographers' Association to take the matter, but unfortunately it is not a sufficiently large body to bear the necessary expenses.

## COLOUR PRINTING AT EARL'S COURT.

THOSE overworked martyrs to whom an evening's relaxation is seldom, if ever, granted may, if they will, find an excellent excuse for a visit to the Austrian Exhibition in the display of examples of pictorial printing by methods that are indebted to photography. The study of these prints, arranged in cubicles around the Imperial Court, may form a peg upon which to hang an hour's enjoyment in the open air, beneath a blue sky bejewelled with fairy lamps, amidst the music of the band and the fragrance of cigars. These distractions, to say nothing of light laughter, *frou frou*, and a hundred perfumes, will not be found to dull the enjoyment of the colour prints. On the contrary, the fact of the critical sense being slightly submerged beneath the optimism of a gala night affords the appreciative faculty fuller scope.

The visitor will be struck by the undoubted merit of the examples. Should he ask himself whether an exhibition of reproductive work got together by British firms (those who do not send their work abroad) could surpass this in quality, he would be forced to admit that it could not. There is, in all the proofs shown, unmistakable evidence of the employment of men of taste and skill: we might venture to add, of artistic training. The key of the situation lies in that fact. Those of us who have had to do with the reproductive arts in this country know how often proofs pass and repass on account of blemishes so obvious that the wonder is that such proofs could ever have been submitted. Your Britisher usually has to be told inch by inch; the customer acting as foreman printer. Your Continental can show his customer what is wanted. His intelligence, his infinite capacity for taking pains, and his general nativeness, usually bring about a satisfactory result at the first essay. At least, this is so when he respects his customer. I have known of firms who, possessing a reputation of the highest kind, nevertheless allow anything to go to the English printers for whom they work, assuring themselves that "the English don't know any better." This is a shameful state of things; but it is undeniable. In a general way, the English *don't* know any better. The few who do lament the backwardness of the native engraver and printer, and go directly abroad for their goods.

Perhaps the present exhibition will give a fillip to British efforts. It may induce them to employ artists as overseers and directors, and it may bring them to the knowledge of this great fact: that it pays to employ brains.

As was to be expected in an exhibition of Austrian work, Vienna makes the bravest show, Prague coming next in importance. All the well-known firms send a choice selection. Particularly good are the specimens of four-colour printing, a method not worked in this country to any great extent, though examples of it are common enough, passing for three-colour work to the uninitiated. Amongst these are often the much-admired plates that adorn "The Studio," which are printed in Vienna by Messrs. Angerer and Göschl for the most part. This firm enjoys the lion's share of British patronage. It shows at the exhibition some triumphs of reproduction. For

half-tone blocks in copper and zinc its reputation is established.

The "Printing Office of the Imperial Royal Austrian Court and State" excels in the combination of photo- and chromolithography: heliogravure reproduced on stone and combined with chromo-lithography. The work from this State presents eminently artistic and interesting. There is also the "Imperial Royal College of Graphic Art," which sends all varieties of photo-engraving and combination printing, as well as "Graphic Impressions," whatever they may be. We do remember to have been arrested by their difference from surrounding proofs. Perhaps their name is merely 'falsin' for the common fuzzygraph.\*

Messrs. Husnik and Hausler, of Prague, were at one time represented by a branch, or office, in London; but they claim no such distinction in the present catalogue,† where they advertise themselves as making "Printing Blocks for one, two, and more colours in acknowledged prominent quality." Indeed, the English in the catalogue is a constant joy to the literary vulture, and makes a dry book well worth sixpence asked for it.

J. Löwy, of Vienna, is another household word here, and his excellent results in colour blocks and coloured collages should be seen and duly admired.

"Three-colour and four-colour prints in most faithful execution; Zincography in finest Autotype and brush manner, etc., etc.," is some indication of the *superlative* work done by the "Establishment for Experiments of the Graphic Art" in Prague, whilst the "Rotary Multiplying of Photographic Pictures in the Bromide of Silver Process" is the chief work of the Austrian Photographic Association in Vienna. Another firm makes a charmingly naïve distinction in the phrase "Export of Fine and Finest Playing Cards."

Carl Pietzner, who describes himself, amongst other things, as a "Grossbritannischer Hofphotograph," has a system of "Pietzner's Colour Photographs," for which he has applied for patents in all countries. Our investigators should know about it. Another startling invention is an "apparatus for the systematic alteration or distortion of plane pictures by images by means of an ordinary photograph lens." The arrangement is on view (!) shut up in its box, which resembles the polished cover of a sewing machine. It is accompanied by a collection of "photogrammes showing the value of the method for various purposes." This device is exhibited by Theodore Scheimpflug, of Vienna, and is patented in Austria, England, France, and America. It is certainly very ingenious. The most useful and satisfactory results seem to be the photographic flattening out of pictures that are upon curved surfaces, such as frescoes upon soffits, pendentives, domes, and so forth. No matter what shape the originals, all the lines in the results have proper verticals and horizontals apparent at a glance, as one would see them piecemeal at very close quarters.

\* Probably photogravures.—Eds. B.J.P.

† We believe Mr. F. C. Clarkson, of Colchester, represents them.—Eds. B.J.P.

From the Bohemian Graphic Society, "Unie," Limited, Prague, comes another wonder, "copper blocks without screen, giving exact facsimile of the original." This is presumably something upon the principle of the "Nature Grain" that Messrs. A. and C. Dawson brought out many years ago. The colour work of "Unie," Limited, is highly commendable and artistic. But, indeed, this may be said of practically all the exhibits in this section. In one or two cases an original is hung side by side with its reproduction, and though to the sharp and knowing eye there may perhaps be a shade of difference between them, yet at the distance of a few feet it is impossible to say which of the two is the original. After all, this is the proper test. A print may be made to look very charming, and, in a book or magazine, may be entirely seductive; but it may be very unlike the original from which it was copied. In my experience, originals are never sent back with proofs for approval; they always have to be specially asked for.

In the majority of proofs shown without originals in this interesting exhibition, however, one is conscious of a fine colour sense upon the part of the makers. The purple, or red, or yellow all-overishness which mars so much three-colour work, the inherently "bad colour," as the artist knows it, which has earned the process the stigmatisation of being called "rubbish," is delightfully absent. This is probably due in many cases to the fourth printing. A delicate light tint of blue, for instance, such as a tender sky may demand, is an

impossibility when there are only small dots of dark blue far apart to give it; but a pale ink pretty fully applied is a different matter. When this is pressed into service, the dark dots are free to do their shading duty in other parts without hurt to delicate passages. Of course, this method may mock all the theories and outrage the theorists; but when it comes to actual commercial practicality, how much are the theories of enthusiasts allowed to count? Is it not a fact that block makers are to this hour seeking their salvation in new and yet newer experiments in colour-filters with one hand, whilst they are turning out their marketable work with the other? Is it not a fact that the blocks are fine-etched, retouched, unmounted and knocked up from behind, burnished, tooled, and otherwise licked into shape, and all this in accordance with the customer's grumbles? Are there three ideal inks for all purposes in daily and universal use? Truly our theories are out of reach at present. They are proper and inspiring on the rostrum, or before the scientific prosenium; but behind the scenes we are "fine-etching" for dear life. "Fine etching" is the confession of a theoretical breakdown. More over, in this country it is the bane of artistic work, because as a rule the etcher himself is not fine enough. He frequently begins his career with a broom, or fetches in an array of cans on a broomstick at midday, and if he is a good boy and his cans are reasonably full he becomes promoted to the post of fine-etcher in time. They do these things differently in Germany.

F. C. TILNEY.

## THE INFLUENCE OF WATTS ON PORTRAITURE.

WITH the passing away of George Frederick Watts, the world was left the poorer of one of the sublimest painters that ever lived; a man whose whole existence was consecrated to art in order that through its medium he could preach great lessons of eternal truth that would be for all time intelligible, not only to the savage, but also to the cultured classes. The period in which Watts flourished was one in which some of the greatest of Englishmen lived; it was a period in which men acted up to what they believed to be right, and did not hesitate to mount the pulpit and publicly proclaim their faith.

### "A Sense of Joyful Austerity."

Born in the year 1817, and brought into contact with the greatest poets, philosophers, and statesmen of the day, it is not to be wondered at that Watts's nature became imbued and actively responded to the dicta of the Victorian era, and that he had the courage to preach his opinions and sentiments in his own inimitable manner, with the same certainty which distinguished the great Victorians from those who have come after them. It must not be supposed from the above that Watts was an aggressive character; on the contrary, no humbler or more peaceful man ever breathed, nor one who was more ready to depreciate the value of his work; but this great painter belonged to that school of men who regarded themselves as merely spokes in the wheel of life viewed as a whole, as opposed to the more modern view, which teaches us to look only at art for art's sake, as if art were something separate to itself rather than a detail in the unity of things eternal. It is necessary to understand Watts's idealism in order to appreciate and properly construe his work, for it is this spirit of cosmic utilitarianism which is to be found in all his canvases, and it was the keynote of his existence. I have seen it often stated that Watts was racially a Celt on account of his family hailing from Hereford, but while this may be true, I cannot agree with those who state that the Celtic spirit predominates his work. On the contrary, I entirely dispute it, and am at one with Mr. G. K. Chesterton in failing to see any signs of the Celtic spirit in Watts's mysticism. Mr. Chesterton, in his biography of Watts, published by Messrs. Duckworth and Co., in their Popular Library of Art, very tersely puts the case as follows: "The essential Celtic spirit in letters

and art may, I think, be defined as a sense of the unbearable beauty of things. The essential spirit of Watts may, I think, be much better expressed as a sense of the joyful austerity of things."

### Watts's Gifts of Idealisation.

Having Celtic blood in my own veins, I can most certainly endorse Mr. Chesterton's opinion, and having made a close study of Watts's pictures, I am of opinion that his definition of the prevalent tone of Watts's work is most fittingly described. In all this artist's work is to be found a vein of seriousness which is antagonistic to that of the pure Celt. He was gifted to the fullest extent with what Matthew Arnold described as "the imaginative reason," and he was fond of depicting robust figures. This we see in the strong back of "Eve Repentant," and in the great heavy hands of his "Mammon," to mention only two instances. Neither of these subjects would have been treated in such a way by a pure Celt, for he would certainly have preferred a frailer and more elfish representation. It is said of Watts that when he gained the Academy Scholarship, which gave him the opportunity of going to Italy to study his art, he never painted in the galleries! He merely wandered through them, and went home to work out his own dreams; he was no copyist, but was so imbued with the spirit of mysticism that he could see nothing or think of anything without forming his own ideas thereon, and, through the medium of his canvas, depicting his ideals for the world to gaze at. It is this deep poetical spirit that manifests itself in his portraiture and which raised it so far above the ordinary level of that class of art; it was the foundation of all his work on which his masterly technique was built up. To Watts a face was something more than a mere physiological phenomena—it was the index to the soul and inner mysteries of the personality of the sitter. To him an eye was not a mere organ of vision, the nose an organ for smelling with, nor the mouth simply an organ for eating and speaking with. They indicated far more than this to him, for he regarded them as demonstrative features which were capable of being affected by the character of their owner, and it was his delight to depict these attributes in all his portraits. Thus, in his picture of John Stuart Mill, which Mr. Macmillan regards as "the most exquisitely characteristic of his portraits," one cannot help feeling that the

high placid brow on which thought is so deeply impressed serves not only as the upper part of the philosopher's face, but also as a crown to glorify his precise, thin, and ascetic features. In the case of Dean Stanley, we have most delicately depicted his sensitive lips, which seem so well in keeping with the refined tone of his writings; while, in the portrait of Thomas Carlyle, the rough, fierce, and strangely-marked features admirably depict the attitude of this writer towards the problems of life. There seems to me to be two great things to be remembered in portraiture—truth and beauty—and to his capabilities of blending these together is to be subordinately attributed the success or failure of the artist's work. I say subordinately because it is naturally of far greater importance that the artist be endowed by Nature with both the spirit of truth and that of beauty, and unless these gifts exist within him, then his work, no matter how fine his technique may be, must of necessity only rise to a mediocre level. Of these two attributes undoubtedly the predominant place must be assigned to the spirit of truth, for it is on this gift that he will have to draw for his power of grasping the individuality of his sitter, and unless he can read through into the very inner person of the individual that he is painting, his work will lack force, and will be devoid of life, and will merely be a thing of beauty. It follows, therefore, that the painter must himself be endowed with a strong personality, for otherwise it would be impossible that he could act upon the individuality of his sitter.

It is his duty to interpret and not merely read or copy the face he is painting, and I think I am right in saying that this is a point which only too many photographic portraitists are entirely ignorant of; I would indeed have it regarded as the first theoretical axiom to be embraced and understood by all who essay to become exponents of the art of portraiture.

#### The Power of the Camera.

I am sufficiently an optimist to believe that this capacity of reproducing the individuality of the sitter can be effected as well by the means of the camera as it can through the medium of an artist's brushes. I would even go further and state that I think it can be better done, for once we have got our subject into that condition of repose or activity which we consider essential to the realisation of our conception of him, modern photographic means have placed at our disposal the power to almost instantaneously record it, while the artist has almost invariably to carry a mental impression thereof for a greater or shorter space of time, as the case may be, after his subject has lapsed into a more or less changed mood.

It is interesting to observe, en passant, that the truth of the above remarks has, like most other things, been the result of the process of evolution. Portraiture is as old as the art of painting itself, and we have only to go into any of the museums with which this country is so richly endowed to see on the mummy cases of the Egyptians the desire to perpetuate the features of the individual. In the fourteenth century we see the art carried to a further stage, when the type, rather than the individual itself, was set up as the criterion to be followed by painters. It was not until the fifteenth century that we observe the art of differentiating the individual universally practised, though it need hardly be said that this forms the true basis of all portraiture. As an example of this, at that epoch of the world's history, I may perhaps instance the fact that Signorelli represented himself and Fra Angelico as spectators in one of the frescoes of the "Last Judgment," at Orvieto, and even Rubens gratified the vanity of his patron by including the portrait of Nicholas Rockox on the wings of the altar-piece commissioned by him at Antwerp. In most of these early masterpieces we are struck by the fact that it is only the profile that is represented, and, indeed, it is not until somewhat later that we find the full or three-quarter face depicted.

In the sixteenth century we find that portraiture was practised in a more easy and graceful style, and the stiffness and general rigidity of execution which predominated the works of the early masters gave way before the broadening ideas and general advance of knowledge of that period; but it was not until the Renaissance that we really find the independent portrait established as we understand it to-day. In the early portion of this article I spoke of the effect of the nationality of Watts on the treatment of his pictures, but as it may be thought that I was thinking only of the works he produced

in the later part of his life, when he entirely devoted himself to idyllic painting, I wish to state here that I consider that in his portraits we can also trace exactly the same style of treatment, and I cannot help thinking it was on account of his masterly knowledge of humanity and his sympathetic feelings towards it, that we may to a large extent, attribute his success in later life, when he left entirely to devote himself to his symbolical pictures. And as there can be no better school for an artist than that which, *ab initio*, embraces the close study of men and women in all their various complexities, for it is a field of surpassing variety wherein we brought into contact with the principal actors in the drama of our times, and are thus enabled to see the panorama of life from many points of view.

#### Personality in Portraiture.

How many of us are able to grasp the inner significance of the facility I am unable to say, for it seems to me to bring us down to the question of temperament. If we can respond to the influence around us, and yet, as it were, bring our intuition to act as a sifted medium, we must inevitably make progress, for we shall be educating ourselves to think individually, and thus our work will bear the impress of personality. This is what we find in Watts's portraits; he made it his duty to discover the thoughts of his sitters, and having as it were, saturated himself with their ideas, he let his own individuality act as a complement to theirs, while at the same time retaining its own personality, with the result that his portraits impress us with a force of character which is entirely their own, and which we classify as the product of a genius. To a certain extent we are right in such a classification, but, on the other hand, we must be careful not to let our enthusiasm run away with us, for we should be doing, not only an injustice to ourselves, but also to the object of our admiration. Watts was endowed with an artistic temperament, and it was a labour of love with him to develop it that he was able to use it as a dissecting instrument with which he was enabled to clear away the envelopment of conventionalities, and present to us the soul of the subject as he conceived

#### Watts's Epigram on Photography.

I fear my optimism with regard to the future of photographic portraiture was not shared by Watts, as, according to Mr. M. H. Spielmann, speaking on June 7, 1905, in the Memorial Hall, Manchester, he (Watts) believed "art is genius, photography ingenuous"—nothing more. Watts's remarks on photography to Mr. Spielmann are particularly interesting, and I cannot refrain from quoting him: "The photographic lens will accomplish the mere copying of nature better and far more accurately than I or any other artist can ever hope to do. But it is the soul that a man puts upon the canvas for the delight and improvement of his fellow man that the lens cannot accomplish, and this cannot be done without full and proper, and I may say, the only, study; for the expression of that art could only become ridiculous and grotesque if the structure were not truthfully placed before the spectator." Well, I suppose we could hardly expect such a great artist as Watts to say more than this, but I cannot help feeling that there are many fine examples of photographic portraiture in existence which show a good deal more "soul" in them, than some of the pictures exhibited at Burlington House; but I certainly grant that they are the exception, and are, alas! all too few and far between.

Now, why is this the case? Well, I think there are several reasons for it. The chief one seems to me to be that the majority of men who make portrait photography their profession have not studied art sufficiently; in other words, they rely on the camera to make up for their deficient training. It is obvious that the result can only be disappointment. It seems that if they but master the techniques of photography they are quite satisfied, and consider themselves justifiably entitled to be regarded as photographic artists, an obnoxious term which is all too common in the profession; the fact that there are techniques in art of a far more complicated character than those in photography pure and simple is, to a very great extent, entirely overlooked by them. I am glad, however, to note that this is an error which is by no means so common now as it used to be, and the photographic press in this country is to be sincerely congratulated on the splendid way it is spreading abroad the truisms of art, and, moreover, the expansion of our public art

eries is doing more than probably anything else to spread a love of art among the people, with the result that they are becoming more exacting in their demands when they decide to "have their photographs taken." It was only quite recently that I was discussing this point with an American gentleman, whose connection with the trade has brought him into intimate contact with the most celebrated professional photographers in this country and in America, and it was not very long before we got involved in a discussion on the subject of the progress of photographic portraiture. He was strongly of opinion that his own countrymen were superior to ours in this field of energy, and considered that this was due to their greater willingness to exchange ideas with each other and their individual eagerness to be shown and to learn everything which could improve their work. He was particularly down on those who went in for the so-called "impressionistic" style, and somewhat dogmatically stated he regarded them as either mentally deficient or sluggish who strove for effect at the least possible expenditure of energy. I remember him showing me some half-dozen specimens of what are known as Rembrandt effects, which brought forth a storm of derision from his lips; in no single instance was there any transparency in the shadows, but these were hopelessly looked up until, to a practised eye, the result was an utterly inartistic anduddy production. Do you suppose this great artist ever turned out such work? I can assure you he never did, and, if you only carefully examine one of his masterpieces and make allowance for the accumulation of the dust of many years, you will quickly realise that his shadows contain the requisite amount of detail and transparency to give the necessary effect of living existence to the subject.

### Study Art—and Humanity

Well, so much for the need of a thorough knowledge of art techniques; I would now wish to impress on my readers the necessity of training and exercising those faculties of temperament with which they may be endowed, for it is this spirit which can only give life and individuality to their work. If you cannot feel yourself, how can you expect to define emotion in your pictures? If you cannot see the strong points of a face, which seem to predominate the whole head, how can you expect to give these their proper value in your production? You must approach your subject with a feeling of reverence, as Watts did, and train yourself to allow the individuality of the sitter to impress itself on you and to respond to it, for if you can do this you will be able to accord it that treatment which will result in your work being something more than a mere facsimile copy of the subject.

To a great extent Watts went further than this, in that he was a hero worshipper, and invariably allowed his enthusiasm to take such a hold of him that he more or less idealised the men he painted. A great man to him was something more than a mere hero; in fact,

he was awestruck with the possibility that any human being could be so wonderful, to assume, as it were, the very attributes of humanity itself, and it is his way of regarding men and women which seems to me to be the influence of Watts on portraiture; he has taught us to regard a great man as something more than a highly developed creature of flesh and blood, and has made us regard him as an embodiment of humanity itself. Mr. Chesterton considers that he overdoes it. Thus, to again quote him, he writes: "Tennyson, fine as he was, both physically and mentally, was not quite so much of a demi-god as Watts's splendid pictures would seem to suggest. Many other sitters have been subjected, past all recognition, to this kind of devout and ethereal caricature." This may be so, but to me, at least, it is infinitely preferable to its antithesis, the arrogant display of mere technique; the latter is hard and cold, the former warm and full of melody. It is comparable to the difference in the style of two musical performers. One may be many times over the greater master of his instrument, but all his endeavours seem concentrated on the mere correct manipulation of the piece he is playing, leaving a feeling of harshness and want in our minds; while the other, even in the performance of the simplest piece, seems to endow it with the very spirit of music, and is capable of arousing in us either a feeling of rebellion or of infinite calm, just as he pleases. Each man has his own tastes, and everyone must decide for himself what his choice will be; but to achieve success we must make up our minds to be always willing, nay, ready, to learn and to seize every opportunity to study the masterpieces of those who have achieved fame in our own field of work. A careful study of Watts's pictures, with Mr. Chesterton and Mr. Macmillan as our guides, will more than repay the time devoted to it, even if it only makes us love humanity a little more than we do, and causes us to realise our proper place in the intellectual and moral systems of this world. In conclusion, let me quote the lines of Colton on "The Road to Glory":—"The road to glory would cease to be arduous if it were trite and trodden; and great minds must be ready, not only to take opportunities, but to make them. Alexander dragged the Pythian priestess to the temple on a forbidden day. She exclaimed: 'My son, thou art invincible!' which was oracle enough for him. Those who start for human glory, like the mettled hounds of Actæon, must pursue the game, not only where there is a path, but where there is none. They must be able to conquer the earth like Cæsar, or to fall down and kiss it like Brutus, or, like Nelson, to snatch the laurels of Victory while she is hesitating where to bestow them. That policy that can strike only while the iron is hot will be overcome by that perseverance which, like Cromwell's, can make the iron hot by striking; and he that can only rule the storm must yield to him who can both raise and rule it."

A. V. KENAH, A.C.A.

## THREE - COLOUR SCREENS AND INKS.

M. LOUIS GEISLER points out in the current issue of "Le Procédé," that the coefficient of a filter, or the factor by which the exposure should be multiplied when no screen is used, depends upon the screen, the plate, and the light.

Obviously, a plate which has twice the red sensitiveness of another will require half the exposure under an orange screen, all things being equal, although both plates may require the same exposure for a black and white object without a filter. In the same way it will be found that there will be considerable variations in the exposure for the same plate under the same filter if, for the ordinary carbons in an arc lamp, the enriched carbons which give a bright orange light, rich in red rays, are substituted.

The method which has been usually adopted to determine the variation in exposure has been merely one of trial and error in photographing a scale of greys ranging from black to white. This method, however, necessitates a considerable number of exposures; it is long and tedious, and frequently neglected altogether in practice.

The instrument the author has used is founded on that applied by M. Cousin, engineer-in-chief of the mines at Nancy, to compare the luminosity of lenses.

The chief part is a circular disc pierced with one or more aper-

tures of a given shape, so that during one rotation of the disc the sensitive plate shall receive at different points along a radius light increasing in a given progression from one margin. For instance, with the disc shown in Fig. 1 the quantity of light increases from the least exposure in the ratio shown in Fig. 2, and from this it is seen that it increases in geometrical progression of the arcs of the circumference included in the apertures, so that the result is equivalent to that obtained by the sensitometric systems of Hurter and Driffield and Scheiner.

In order to make the apparatus as convenient as possible, it is given the form of a dark slide, and the general arrangement is shown in Fig. 3. Immediately at the back of the shutter slide is a frame-work which will take three screens, E, E<sup>1</sup>; whilst the fourth aperture is left without a screen so that the naked plate can be tested; or it may obviously carry a fourth screen if desired. At the back of the slide is a gun-metal disc C, through which passes the spindle on which the sector C revolves; in A A are four grooves which take four slides in which are placed the plates G, G<sup>1</sup>, protected at back by V, V<sup>1</sup>. P is a pulley attached to the spindle, which may be actuated by a motor or multiplying wheel.

To avoid reflections from any source of light save that which is to

be tested, it is convenient to fit this apparatus to a camera, which should be directed to a white surface uniformly illuminated by the light to be used. For very exact measurements, and to avoid any error due to the decrease of illumination towards the margins, the lens and camera front should be removed. Provided the sector wheel revolves sufficiently rapidly, that is, from 500 to 800 times a minute, the error of intermittent illumination is negligible.

Fig. 1.

The sector should be rapidly revolved, the shutter of the slide removed, and the exposure made. Development is effected as usual, all four plates being developed together, and development should be continued till that portion which has received the least exposure is distinctly grey.

After the usual operations of fixing, washing and drying, the negatives should be cut along one of the radii of the disc, which is

Fig. 2.

distinctly marked by notches in the rebate of the plate carriers. Each negative exposed behind the screens is successively compared side by side with that exposed without a screen till the densities are equal, then the distance between the edges of the least exposed parts is a measure in terms of the scale Fig. 2 of the light received, and is the ratio of exposures. The scale can, of course, be graduated in millimetres or actual terms of the coefficients.

Fig. 3.

A similar apparatus may be used for testing liquid filters.

It may be interesting also to describe a method which has been employed for some years for the determination of the intensity of three-colour inks, with the view of obtaining blacks and greys without the predominance of one or other of the colours. This instrument was devised by M. Rosensthiel, who calls it a "colour balance" (Fig. 4), but these trials may be made without any special apparatus by merely using an electric motor or any arrangement which carries an arm revolving at a high speed. On this arm are

fixed discs pierced at the centre and along one radius (Fig. 5), similarly to those employed by Maxwell in his experiments on the mixture of colours. Two or three of these discs may be combined (Fig. 6), and the angles of each altered at will, so as to obtain combinations of the colours in all proportions.

Cards are covered with the inks to be tested in full intensity and fastened in equal angles by a screw, nut, or button to the arm

Fig. 4.

revolving, and the predominance of one or other of the colours looked for. The angles must be altered till a perfectly neutral grey tint is obtained. If this cannot be obtained the inks should be rejected. Supposing, Fig. 7, that to obtain a neutral tint the angles of the cards were respectively yellow 120 degs., red 140 deg. blue 100 degs., it is proved at once that the yellow and blue are

Fig. 5.

more saturated than the red. To obtain equilibrium we must reduce the intensity of the blue and the yellow by diluting the inks with varnish, and the ratio of the angles tells us precisely in what proportions we must do this. Comparing the red, the least saturated colour with the others, we can write:—

$$\begin{array}{l} \text{for blue} \quad \frac{\text{actual intensity}}{\text{highest intensity}} = \frac{140 \text{ deg.}}{100 \text{ deg.}} \\ \text{for yellow} \quad \frac{\text{actual intensity}}{\text{highest intensity}} = \frac{140 \text{ deg.}}{120 \text{ deg.}} \end{array}$$

We ought then to mix 100 parts of the blue ink with 40 parts of varnish and 120 parts of the yellow, with 20 parts of varnish to obtain in each case 140 parts of tint, which should be used.

The correctness of the results thus obtained can be checked by coating cards with the corrected inks, and proceeding as above; i

correct, a neutral grey will be obtained with sector angles of 120 degs. for each colour.

The want of transparency in the inks frequently obliges one to take into consideration in this regulation the order of printing. If they are printed in the usual order, yellow, red, and blue, it may be necessary in order to obtain perfect adjustment to make the angle

Fig. 6.

for yellow slightly larger than 120 degs., and that for the blue slightly less. The angles having been once determined it will be sufficient to adhere to these for any subsequent testing of the same type of inks.

It is easy to determine the intensity of the black which will be obtained by the use of the inks by comparing the grey which is obtained with the colours with that got by using a black and white disc, the former having an angle of 120 degs. The value to be given to the black sector to obtain equality is always less than this. Supposing that we conclude that the intensity of black by superposition is 110-120 degs., it will then be 9-10 degs. of that black

taken for the comparison, and assuming that other qualities are equal, one ought evidently to choose, from the point of view of the

Red.

Blue.

Fig. 7.

ease of production of black, those inks which give the nearest approach to unity.

## THE LAWS OF THE STEREOSCOPE AND STEREOSCOPIC TRUTH.

11.

### The Vigorous Consequence of the Stereoscopic Laws.

We now see that the convergence of the eyes and the lenses is the essential element in stereoscopy. If we wish to faithfully reproduce by the lenses that which we see with the eyes, then the axis of the eyes must converge towards the subject; the axis of the lenses ought theoretically to converge in the same manner. These instruments could not then be mounted on one and the same front, which is the invariable plan. Each of the lenses ought then to be mounted on an independent camera, fixed by the aid of a pivot on one common base in such a manner to permit of the lenses being placed closer together as the angle of convergence increased. In one word, the apparatus should be capable of the same movements as the eyes.

From the absolutely theoretical point of view, and pushing the striving for truth to its extreme limits, one ought at the same time to recognise, as the consequence of the above, that if the lenses cannot occupy the same plane, which would be excluded by their convergence, and not permitted by their being placed closer together, the negatives could not also be in the same plane. Consequently, as the positives ought to be seen by convergence and perpendicularly to their surfaces, the double stereoscopic print ought to have a fold in the middle. Finally, if one uses lenses to enlarge the images much reduced by apparatus of short focus, the axis of these lenses ought to correspond also to the convergent visual rays, and the ideal stereoscope would present the following conditions.

S (Fig. 6) is a sphere photographed stereoscopically by the lenses G D, separated rather less than 6.5 cm., since 6.5 cm. corresponds to the distance of separation of the eyes looking at the horizon, in which case the visual rays are practically parallel. The two negatives,  $s$   $s^1$ , having given the two prints,  $a^1$   $c^1$ ,  $A^1$   $C^1$ ; to see these images which form the stereogram having an angle in the middle, the eyes should be placed at G D, and if lenses were used, their plane ought to be respectively parallel to the plane of the objectives, G D.

This diagram shows that, contrary to the opinion generally received, the images of a stereoscopic couple are never superimposed in the stereoscope; it is sufficient that they should appear slightly nearer to one another than the separation of the eyes, in such a manner to fill for each eye the angle occupied by the object seen in nature, which, in our case, is the sphere S.

One can enunciate this truth in a very striking manner by saying that if the stereoscopic couple were transparent and placed between the spectator and the subject, it ought to exactly cover the latter, and correspond for each eye with nature itself.

Fig. 6.

The above represents the absolute theory of stereoscopy in all its rigorously. From the point of view of practical photography, an ordinary stereoscopic camera renders the natural truth with sufficient approximation if the lenses are separated by the natural dis-

tance of 6.6 cm. For portraits, especially, one cannot exceed this separation, for, in the human figure, the least deformation is perceived.

Before proving by comparative stereoscopic prints the absolute truth of the laws which we have formulated, we will proceed to give the graphic explanation with the aid of the following figures:

G and D are the two eyes; the normal vision of the object A B is represented by the continuous lines. The distance of the object from the eyes being G S or D S, the visual angle of convergence is G S D. It is not shown in the figure, to avoid complication. The photograph of the object made with the lenses placed at G and D, gives the exact representation of the distance S, and the dimensions A B. If the lenses are placed closer together, and the photograph is made with them at the points  $g$   $d$ , the angle of convergence  $g$  S  $d$  is smaller

stereoscopic laws above. In Fig. 8 the stereogram which represents the stereoscopic prints is supposed to be at E P.

It will be seen that the two elements of each couple ought to be mounted one to the other in such a manner so as to be seen with the desired angle of convergence.

In Figs. 7 and 8, three stereograms are made at the same distance from the subject, but with different convergences. In Fig. 9 the distance of the subject alters, but the convergence remains the same. Normal vision is represented by the continuous lines; the eyes are at G D, and see the object A B at the distance D S. If A B is photographed with the same convergence, but closer, the lenses must be shifted to  $g$   $d$ . But, again, to see the image, the right eye ought to see it from the point  $d$   $r$ , and the object will be at the distance  $d$   $r$  S<sup>1</sup> = D S, but it will appear larger than in nature.

Fig. 7.

Fig. 9.

than G S D. But the eyes cannot be displaced to  $g$   $d$  to see the images; if the left eye placed at  $g$  does not move, it must shift the angle  $A$   $d$  B to  $A^1$   $d$   $r$  B<sup>1</sup>, so that its apex enters the right eye, for we suppose the distance,  $g$   $d$   $r$  = G D equal to the separation of the eyes. But when the fusion of the two images of A B will be advanced to  $A^1$  B<sup>1</sup>, the object will appear more distant and larger than in nature. If, on the contrary, the lenses are separated to G<sup>1</sup> D<sup>1</sup>, the angle of convergence G<sup>1</sup> S D<sup>1</sup> is greater than G S D; but to see the image the right eye ought to be placed at D R, the left eye being at G<sup>1</sup>; in fact, G<sup>1</sup> D R is equal to the separation of the eyes G D. But, then, the images will combine at a b, and the object will seem closer and smaller than in nature.

Figure 8 is the conclusion of the above; the three convergences  $y$  are shown starting from the same points G D, representing the eyes. One will immediately recognise in this figure the perspective of the three vertical planes figured by the stereogram which preceded the

Fig. 10.

Fig. 8.

Fig. 11.  
Fig. 12.

On the other hand, if the photograph is taken from the points G<sup>1</sup> D<sup>1</sup>, the right eye cannot see the image of the right, except from the point D R, and the object will appear at  $s$  at the distance  $s$  D R = S D, but it will appear smaller than reality.

Fig. 9 shows how certain people deceive themselves into believing that it is sufficient to lessen the separation of the lenses to photograph a small object very close. They would only be right if the object was a geometrical point which has no dimensions, and, consequently, no lines in perspective. Small objects, if one would have them reproduced as they are, ought to be photographed like larger ones, at the distance at which they are to be seen, and with a lens separation equal to that of the eyes.

One does not see much at a lesser distance than ten or a dozen centimetres, with an angle of convergence of about 30 degs. But when one photographs at this distance, with lenses of extremely short focus, the image runs a great risk of being larger than nature, and, conse-

ly, the composition of the stereoscopic couple ought to be imitable in the ordinary way.

Supposing, in fact, Fig. 10, an object, A B, seen and stereoscopically photographed very close, the eyes and the lenses being placed at D. It may be possible, for the images,  $b$  a,  $b^1$   $a^1$ , may be larger in nature, and as they ought to be viewed—as always—at the distance of the lenses to have true perspective, it is necessary to place them further from the eyes than the distance D S, and as they are to be viewed with the angle of convergence G S D, the image

give, to those who still feel inclined to contradict, the opinion of one of our leading opticians on the separation of lenses greater than the separation of the eyes.

Speaking in his catalogue of his prismatic binoculars, he says actually: "Les stéréos-jumelles à prismes Krauss sont disposées de belle façon que l'écart des objectifs soit plus grand que l'écart des oculaires. Il en résulte un effet stéréoscopique augmenté. L'image est ainsi à la fois plus agréable et plus utile." Unfortunately, at the end he ceases to be correct, and as regards the greater utility we

Fig. 13.

Fig. 14.

ended for the right eye ought to be placed at  $a^{11}$   $b^{11}$  at the left that intended for the left eye.

Under these conditions, in virtue of our first law, the stereoscopic vision will be located at A B in conformity with reality.

As in Fig. 11, the images are reproduced of the natural size, there is no means of forming the stereoscopic couple, the two images ought to occupy the same place, A B. It is necessary then to use expedients, to mount the images side by side, and superimpose them; this is a case in which to call in the aid of achromatic prisms P F. We know that the prisms distort the images in opposite directions, and the fusion will not be satisfactory.

It would be better then, in a parallel case, to effect the fusion—by aid of two mirrors M M, of which the inclination determines the place to be occupied by the images, in such fashion that the distance  $G M + M b^{11} = G B$ . Only by this system the object is reversed as regards right and left, unless the negatives have been reversed through the glass of the plate reversed in the dark slide.

Before passing to the experimental proof by stereoscopic photography of all that we wish to establish, it may be permitted us to

should be happy to know this. M. Krauss also adds: "Pour le théâtre où l'effet stéréoscopique trop accentuée eût été plutôt nuisible,

Fig. 15.

nous construisons notre jumelle avec l'écart des objectifs égal à celui des oculaires," that is to say, equal to that of the eyes.

(To be continued.)

A. GODERUS.

## DEATH OF M. LEON VIDAL.

We regret to announce the sudden death of Mons. Leon Vidal, at Port de Bouc, on the 5th of August. His loss will be universally deplored in photographic circles, for he was known by his writings during the last thirty years, and esteemed by his many friends all over the world.

To ourselves the loss of M. Vidal is one which we shall keenly feel, for we had reason to value his kindness and camaraderie in many ways. Of late years, colour-photography had absorbed a large proportion of M. Vidal's leisure. He took very great interest in the exhibition held at THE BRITISH JOURNAL OF PHOTOGRAPHY in the early part of this year, and subsequently made several communications to our pages on the subject. Always a fluent writer, his pen was never idle when he believed he was furthering the advance of photography.

The following appreciation of M. Vidal, by one who has known him for more than twenty-five years, is kindly sent to us for publication:—

Few men have more fully recognised the educational value of photography, or done more for the development of photo-mechanical work and the practical application of permanent printing processes for book illustration than he did. His parents were proprietors of the salt works at Port de Bouc, near Marseilles. He was educated as an engineer at the Lycée, St. Louis, but preferred the laboratories of the Sorbonne, becoming preparator to Dutas and Claude Bernard, and so coming into touch with the great savants, his contemporaries. In the summer he superintended the salt collection at his home, and made over the mother liquors, saturated with iodine and bromine, to Poitevin, who was then director and chemist of a neighbouring salt factory. He also interested himself in the researches of the great inventor of many modern photo-mechanical methods, and there can be little doubt that from this intimacy with Poitevin he was led to identify himself so specially with the practical development of these methods. In the winter he passed his time between the Sorbonne and the ateliers of the principal Parisian photographers, urging them to adopt permanent printing processes and those most suitable for book illustration, a subject to which he entirely devoted his energies. This practice of spending his summers in the south and his winters in Paris was continued to the last.

He was the author of several practical treatises on photographic and photo-mechanical subjects, among them "Calcul des Temps de Pose ou Tables Photométriques, 1865, 2nd edition, 1884; "Photographie au Charbon," 1869, 2nd edition, 1870, 3rd, 1877; "Traité Pratique de Phototypie," 1879; "La Photographie Appliquée aux Arts de Reproduction," 1880; "Traité Pratique de Photoglyptie," 1881; "Cours de Reproductions Industrielles," 1882; "Manuel du Touriste Photographe," 2 vols., 1885, 2nd edition, 1889; "La Photographie des Débutants," 1890; "Manuel Pratique d'Orthochromatisme," 1891; "Traité Pratique de Photolithographie," 1893; "Photographie des Couleurs," 1897; "Traité Pratique de Photogravure," 1900; and "Photochromie," 1903.

After the death of Poitevin his family confided to M. Vidal the publication of his photographic work, and the result was a new edition, in 1883, of the "Traité des Impressions Photographiques," revised and enriched with valuable notes and appendices.

In 1879 he took over the direction of the "Moniteur de la Photographie" shortly after the death of his friend Ernest Lacan, and ably edited it until last year, when he gave it over to M. Charles Gravier, with whom he had been associated for many years, and to whom the writer is indebted for much of this information regarding his old friend. In 1879, M. Vidal also succeeded M. Lacan as French correspondent of the "Photographic News," a position he held until comparatively recently. He was also a constant contributor to many photographic journals and publications in this and other countries.

He worked out the polychrome method of colour printing, founded on the Woodbury process, but like it, now superseded by simpler methods. It was, however, very suitable for the purposes intended of reproduction of jewellery, fine fabrics, porcelains, etc., with their colours and metallic lustre. Under his direction also some very fine albums of reproductions in collotype were brought out.

He was a Chevalier of the Legion of Honour, Officer of Public Instruction, and since 1879 was Professor at the Schools of Decorative Arts in Paris and Limoges, and delivered regular courses of lectures on processes of photographic reproduction.

In 1861 he created the Photographic Society of Marseilles, was President of the "Chambre Syndicale de Photographie" from 1886 to 1890. He was a member of the Société Académique de Marseilles, honorary member of the principal French photographic societies, and was elected an Honorary Fellow of the Royal Photographic Society in March last. In 1889 he started a society of mutual assistance, L'Union Photographique; later, the Société Photographiques Documentaires, and in this connection did good service to the Royal Photographic Society by obtaining for it the loan of several valuable specimens of early French photographic process for the Crystal Palace Exhibition in 1898. Four years ago he promoted the "Société de Photochromie." He was latterly particularly interested in the development of colour-photography, and was constantly working at it.

A man of most kindly and generous nature, he had many friends in all parts of the world, and was always ready to help them in anything the cause he had so much at heart. He leaves a widow and one son to mourn his loss.

## PHOTOGRAPHING FOSSILS.

We read in "The Camera" that the Folmer and Schwing Company, of Rochester, N.Y., has designed and built for the United States Geological Survey a special piece of photographic apparatus for photographing fossils, or other similar objects. In this apparatus the Survey use what is known as "the Williams' process." This method was worked out by Professor Henry S. Williams and his assistant, Mr. W. Carkhuff, and consists in an elimination of the colour of the fossil by a process of sublimation. Fossils cannot be photographed for scientific purposes in a haphazard manner. There

certain characteristics that must always be orientated in relation to the same position and illuminated in the same way in order to produce results of any practical value to the scientist. Some of these fossils are photographed at same size, while others are enlarged; great accuracy is required in this particular. As some of these fossils are exceedingly small and delicate, it is obvious that to do the work economically special apparatus is required. On a comparison be made between the first piece of apparatus used by the original experimenters with the apparatus just completed, a remarkable evolution in scientific camera building, as practised at the present time by the Folmer and Schwing Company, would command unbounded admiration. This special camera is mounted on a tilting base, so arranged that the camera may be elevated or lowered to any desired position, in order to secure the proper lighting of the subject. The operator can make any of the following adjustments on camera or subject without leaving his natural position while consulting the focussing screen; move the subject to and from the lens or revolve the subject support; move the camera horizontally or forth on the tilting stand, raise, or lower, or shift the front of the camera in either direction; revolve the back from a horizontal to a vertical position, or to any intermediate point; elevate or lower the subject support, in order to secure the proper lighting, by mechanical devices. The base of the stand contains two cabinets

storing lenses or small parts. The focal capacity of the camera, including cone extension, is 7½ feet. Length of stand top, with erect support and camera extended, 11 ft. Size of plate, 6½ by 4½ by 4.

## Patent News.

process patents—applications and specifications—are treated in *Photo Mechanical Notes*."

The following applications have been made for Patents from August 7 to August 11:—

IN CAMERAS.—No. 17,745. Improvements in hand cameras. P. M. Justice, for the Emil Wunsche Aktien Gesellschaft fur Photographische Industrie, Germany.

IN LENSES.—No. 17,955. Improvements in photographic films. Edward Geisler Herbert, 55, Market Street, Manchester.

IN LENSES.—No. 17,989. Improvements in photographic cameras. A. J. Boulton, for Antoine Cardon, France.

IN LENSES.—No. 18,028. Improvements in cameras. Frederick James Wheat, 5, Corporation Street, Birmingham.

IN LENSES.—No. 18,073. Improvements in lenses for photographic and other purposes. Cyril Frederick Lan-Davis, 25, Newman Street, London, W.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

Full specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CATATYPE PRINTING.—No. 10,078. 1906. The invention consists in means for protecting negatives, apparatus, or printing papers from the action of hydrogen peroxide, such means being necessary to prevent the access of hydrogen peroxide vapour to surfaces with which it should not come in contact, in the employment of the peroxide for catatype printing processes. The protecting surfaces may consist of paper, etc., saturated with potassium permanganate or other substances. A. G. Bloxham, for the Neue Photographische Gesellschaft, Berlin.

TELEPHOTO LENSES.—No. 4,523. 1906. The invention is a lens of the telephoto class—i.e., consists of a front positive lens, with a negative lens behind, and resembles telephoto lenses in having a focal length much longer than the distance from lens to focal plane. It is corrected for one definite focal length only. The

Fig. 1.

variation of the focal length being thus dispensed with, it is not necessary to remove, either in the positive element the aberrations characteristic of a simple collective lens—viz., spherical and astigmatic under-correction, or in the negative element the aberrations characteristic of a simple dispersive lens—viz., spherical and astigmatic over-correction, but only to so choose them that they compensate each other. The advantage gained is, that to both individual elements a simple form may be given, and yet in their combination is attained, firstly, satisfactory freedom from astigmatism, curvature of field and distortion, and secondly, at the same time, satisfactory spherical correction for a sufficiently large relative aperture. On the other hand, in the well known tele-objectives, in so far as they can lay claim to correction at all, the front element is always a corrected objective, and, notwithstanding this less simple construction, only the one or the other correction is satisfactorily attained. In objective systems also composed of a front positive element and a back negative element—but which do not fall into that class

known as tele-objectives, because their elements lie close together and the negative element has the greater focal length—the two elements are likewise given spherical aberrations of opposite character. In the more important element, however, that is, the positive one, the spherical under-correction is not, as is the case of the present invention, approximately that of a simple collective lens only, but by means of a collective cemented surface it is raised to a relatively large amount, to compensate which—

Fig. 2.

in contradistinction to the present tele-objective—a simple dispersive lens as back element would no longer suffice. In its simplest form, the new objective consists of two simple lenses, a crown glass meniscus as the positive, and a dispersive lens as the negative element. Satisfactory spherical, astigmatic, and orthoscopic correction is attained herewith. As to chromatic

Fig. 3.

correction, comparatively large aberrations must still remain, so long as the choice of glasses is restricted to those now obtainable. These aberrations are, however, innocuous for several purposes. Chromatic correction is at once attained when both elements are individually corrected chromatically. Without detriment to the other corrections, the extinction of the chromatic

Fig. 4.

aberrations can, however, be almost entirely accomplished by constructing either the front or the back element of two lenses (separated or cemented). By such a three-lens formation of the new objective, all the known errors of the image can be removed to such a degree as to suffice for many purposes. Fig. 1 is an example of the lens, with spherical and astigmatic, but not chromatic, correction, consisting of two simple lenses. In Figs. 2 and 3 all three corrections are made as they are also in Fig. 4, the data for which latter are as follows:—

Radii:	Thicknesses and Distances
$r_1 = +185.5$	$d_1 = 13.7$
$r_2 = \infty$	$b_1 = 3.5$
$r_3 = -137.4$	$b_2 = 13.7$
$r_4 = \infty$	$d_2 = 8.6$
$r_5 = -139.8$	$d_3 = 13.7$
$r_6 = -81.8$	$l = 219.0$
$r_7 = +68.7$	$d_4 = 5.2$
$r_8 = \infty$	$d_5 = 18.2$

#### Kinds of Glass.

$n_D$	$n_G - n_D$
$L_1 : 1.59133$	0.01229
$L_2 : 1.61690$	0.02235
$L_3 : 1.59133$	0.01222

$L_5 : 1.61690$	0.02235

Carl Zeiss, Jena, Germany.

**COLOUR PHOTOGRAPHY.**—No. 15,185. 1906. The invention is a method of obtaining positives or printing plates from the Sampolo-Brasseur negatives, described in English Patent No. 8,290, 1896. These negatives were made through a screen, ruled into a revolving series of orange-red, yellowish-green, and blue-violet lines, and would give colour synthesis by the usual methods. But to obtain colour correct black and white prints a positive is first made and placed in the copying camera, with a black and white screen, ruled as in Fig. 1, which shows a black and white screen placed in contact with a Sampolo-Brasseur positive. It is in such a position as to hide two of the partial images and allow only the red one to be seen. It being the counterpart of the negative shown in Fig. 2, the shading is shown as that of a positive. If this diapositive is copied in the copying camera, exposing it for, say, 30 units of time—then the black and white screen is moved, so as to expose the green image and cover the red—and without moving the negative plate on which the red has already been impressed—exposing this green image for, say, 20 units of time—and then the black and white screen is again moved so as to uncover the blue image and expose this for, say, 10 units of time—then the resulting negative will appear as in Fig. 2. The positive print from this negative will show the orange quite luminous, the green less, and the blue least luminous—which is as it should be in good orthochromatic photography. It is preferred, while making the three exposures for this second negative, to move the negative plate the width of

Fig. 1.

Fig. 2.

two lines in the vertical direction during the exposure of each colour positive, so that each red image is also copied upon those portions of the plate which correspond to the green and blue images of the positive, and similarly for the other partial images. This has the effect that the resulting negative is more brilliant than that produced without shifting the plate. It should be understood that the motion of the negative plate—which in this case is in a vertical direction—is always in the same plane as the plate itself, and in a direction normal to that of the lines. The purpose of this motion—which is repeated while copying each partial image—is to convert the original negative, made up of three partial images, into one negative made up of three whole images. The images are therefore superposed one over the other; as a result there will be no appearance of lines (the resulting fringes being absolutely negligible), and if the relative exposures have been correctly timed, the result obtained is the same as if the negative had been made through three plain unruled monochrome screens, with the exposures so timed as to obtain correct orthochromatic effects. In proceeding in this manner care must, however, be taken to bring the plate back to its original position before exposing the next image on the positive. It is to be noted that the essential difference between this new method and that described in the Patent No. 8,390 of 1896, is that in the new method two or more images (preferably three) of the original negative are copied on one plate, while in the old method described each of the three images constituting the original negative, is copied on a different plate—one for each image. Charles Louis Adrien Brasseur, 10, Fifteenth Street, New York.

**COLOUR SCREENS.**—No. 12,793. 1906. The invention is a line colour filter, provided with monochrome bands of colour designed so

as to indicate variations in the colour sensitiveness of the emulsion. In the drawing the bands *b* indicate one colour—e.g., *r*, *c* another, say yellowish-green, and *d* the third colour, the sequence of colours being maintained across the plate. In the arrangement shown in the figure, the lines *c d* are stopped altogether, or are wholly obscured, at the points *e*, while at points *f*, the lines *b d* are similarly treated, and at the points *g*, the lines *b c* are similarly treated; by preference, spaces *e f g* are placed at each side or end of the screen, the leaving extensions of the several sets of lines in different places on the screens. Or areas *b<sup>1</sup> c<sup>1</sup> d<sup>1</sup>* may be formed across the ends of the lines *b c d*, as indicated in Fig. 2, the colours of the areas *b<sup>1</sup> c<sup>1</sup> d<sup>1</sup>* being the same, respectively, as the colours of the lines *b c d*. The extensions (Fig. 1) may be placed upon the same glass as the screen or upon an independent glass plate, but, in order to ensure exactitude of colours, it is best to employ the first-named method. In either case it suffices, when a new emulsion is used in the process of colour photography to photograph a white surface, and, after development, to examine the deposits in the extensions or areas to see if

opacities are the same. And the same may be done with other colours, the comparison being between the colour of the completed photograph and the colour of the original object, such as a coloured print or a painting. But this complication is unnecessary if the screen is correct theoretically, and one uses an emulsion having the same curve of sensitiveness to the visible spectrum rays. If, on examination, it is found that the deposits are not equal or correct, the old method of correcting the defect is to use a compensating screen behind the objective, and substitute one such compensator for another until correct results are obtained. Such compensators are usually formed of two glasses, one a bluish-red and the other a yellow, whereby the green and the blue-violet, as well as the ultra-violet, have their action cut down or eliminated, as the case may be. But it is much easier to secure these results by the use of the compensators described in a prior application of mine for letters patent in Great Britain, which consist of two glasses, which are placed in the lens, one immediately before, and the other immediately behind, the diaphragm. One glass is tinted a bluish-rose and the other a yellow; the tints of these glasses augment gradually from one edge to the other, and in the direction in which they are moved. These glasses are considerably longer than the greatest diameter of the diaphragm, and each has a rack and pinion whereby it may be moved independently of the other. Indexes permit of the accurate adjustment of these compensators and tables may be used to guide the operator as to the position such compensators should have for different conditions of light atmosphere; or experience may be depended upon. The indexes of course, should show the original positions of the compensators. Charles Adrien Louis Brasseur, 10, Fifteenth Street, New York, U.S.A.

**CINEMATOGRAPH AND PHONOGRAPH.**—No. 2,157. 1906. The invention consists of means for the synchronous operation of combining cinematographs and phonographs, characterised by the fact that

the disposition of two rotating parts, one of which is actuated by the phonograph and the other by the cinematograph, these rotating parts being themselves connected to other visible parts which indicate in what sense it is desirable to modify the speed of the cinematograph in order that it may be synchronous with that of the phonograph. The full text of the specification and the diagrams are necessary for the proper explanation of the six claims. Oskar Messter, 16, Friedrichsstrasse, Berlin; and Leon Gaumont, 57, Rue St. Roche, Paris.

NEMATOGRAPHS.—No. 15,003. 1905. The invention consists of means for preventing or for locating the spread of fire which may occur in the film, consisting in forming on the end of the lens tube or connecting to the latter a chamber, preferably air or gas-tight, guiding means for the film mounted on said chamber, and a hinged door, carrying a subsidiary or second portion of the airtight chamber, and pressure pads and frames of a spring-controlled character carried by the frame of the subsidiary chamber or by the hinged door. Henry William Joy, Peace Field, Cross Lane, Marple, Derbyshire.

New Books.

“TRAITE Pratique de Photographie Stereoscopique.” By Charles Fabre. Paris: Gautier Villars. Price, 6 francs.

For M. Fabre’s services to students of photography in his capacity of editor of the “Traité Encyclopedique,” we have the very highest regard, and we number the volumes in question among the most recent contents of our photographic library. They show that M. Fabre possesses the encyclopædic faculty in a high degree, and it is an account of his very qualification in this respect that the present volume, in our estimation, has lost by attempting too much, has overreached itself in straining to perform a task which was impossible, and, moreover, was not at all useful or necessary. Although a large book of 200 pages, the text which deals with its subject proper, stereoscopic photography, might be contained in a volume at most one-quarter the size. And it would have been all the more valuable to the reader than it is at present, diluted with standard information on photographic processes and manipulation. We could dispense with chapters on intensification and reduction, because, after all, the application of these processes to stereoscopic negatives is not very different from that to any other description of negative. We could dispense with chapters on plate-making just as we do not crave for the incorporation of a treatise on locomotive construction in our Bradshaw. Boiled down and shaken together, a very good exposition of practical stereoscopic photography can be made of the material, for M. Fabre has omitted little, and has even a chapter on stereoscopy in natural colours, and, of course, one on the methods of stereoscopic projection.

The thirty-first volume of the “Aide Memoire,” edited by M. Charles Fabre, reaches us from the publishers, MM. Gautier Villars, 15, Quai des Grands-Augustins, Paris. As in previous issues it contains an epitome of important papers and items of progress of the day, and a directory of photographic societies. One other useful feature is a list of French patents, taken out in the twelve months preceding publication, arranged in chronological order. The price of the “Aide Memoire” is 1fr. 75c. in paper covers, or 2fr. 25c. bound.

New Apparatus, &c.

USERS of Kodaks and Kodak films should welcome the announcement that, with the object of allowing their patrons to have full advantage of the colour sensitiveness of the N.C. and Kodoid films, the Kodak Company have now introduced a light filter, at the low price of 1s. The filter is a thin stained gelatine film, mounted in a metal rim for attachment to the lens hood, and it is made in two intensities—“5 times” and “10 times”—and in four sizes, suitable

for the various sizes of Kodak cameras. The filters submitted to us are highly transparent, and with the Eastman film permit of a high degree of colour correction. A booklet now in preparation by the Kodak Company deals with the use of the filters, and will be sent gratuitously on application to Clerkenwell Road, London, E.C.

New Materials.

THE Kodak Company have now placed upon the market the all-popular sepia toner for bromide and gaslight prints, albeit that for many years they were, and still are, the advocates of the hypo-alum or direct form of sulphide toning. In fact, we think we may say that that process originated, as a practical method, with the Eastman firm, and in their hands has proved as permanent as any silver printing process. The new toning preparation is manifestly based on bleaching with a ferricyanide and bromide mixture, and darkening or “toning” with a weak solution of sulphide of soda. The bleaching mixture is put up in tablets, one of which, in four ounces of water, forms the bath. The stock sulphide solution is mixed with 32 times its volume of water. We have found the preparation to act most quickly on bromide and gaslight prints, and with excellent results. The price of the outfit, which is conveniently put up in a cardboard case, is 1s.

MESSRS. RAINES, of Ealing, send us an example of their latest work in the shape of a boudoir print on “Japine,” the new platinotype paper, from a negative of a full length portrait. A more handsome form of photograph or one more qualified to do credit to the photographer it is difficult to imagine. We gave our opinion of the new paper some time ago, and we are glad to find Messrs. Raines turning out such magnificent work with it.

By the same post we receive from the Platinotype Company a print also in “Japine” of the recent Convention group taken by Mr. Max Mills. The subject is not one which displays the paper to the best advantage, but the two prints which lie before us side by side together supply an eloquent tribute to the new variety of platinotype.

A WEDNESBURY Photographer’s Suicide.—Last week George Lowe (64), a photographer, carver, and gilder, of Russell Street, Wednesbury, was found dead under tragic circumstances. He had been downstairs, but went back to his bedroom, and a few minutes later was found lying across the bed lifeless, while a bottle, labelled “Cyanide of potassium,” was on a dressing table. Deceased, who had been in business for a considerable period, is said to have been depressed through bad trade.

THE exhibition of the South Manchester Photographic Society is announced for December next. The secretaries will send particulars from 43, Lapwing Lane, West Didsbury.

## FORTHCOMING EXHIBITIONS

September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.

November 15 to 27: Burnley Camera Club. Entries close November 10. Sec., Fred Whitaker, Mechanic's Institution, Burnley.

November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismore," Stamford Road, Southsea.

November 20: Sefton Park Photographic Society.—Sec., A. W. Parr, 34, Loudon Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Hon. Sec., W. H. Bone, 32, Sackville Road, Hove.

December 6 to 8: South Manchester Photographic Society. Entries close November 21.—Secs., J. H. Haywood and M. W. Thompson, 45, Lapwing Lane, West Didsbury.

December 11 to 15: Southampton Camera Club.—Hon. Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

1907.

February: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. B. Parnham, "Chagford," Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

October 24 to November 14.—West of England Exhibition (Photographic Section). Entries close October 1. Sec., A. D. Breeze, 41, Union Street, Plymouth.

September 5: Kirkcaldy Photographic Society.—Sec., J. Rowan Thompson, 154, High Street, Kirkcaldy.

October 24 to November 1: Plymouth Exhibitions.—Sec., A. D. Breeze, 41, Union Street, Plymouth.

October 31: Watford Camera Club.—Sec., E. H. Jackson, 100, High Street, Watford.

November 7 to 8: Bedford Camera Club.—Sec., W. H. Hodge, 58, Beaconsfield Street, Bedford.

November 7 to 10: Hackney Photographic Society.—Sec., Walter Selfe, 70, Paragon Road, Hackney.

November 14 to 17: Rugby Photographic Society.—Sec., R. H. Myers, 13, Bridget Street, Rugby.

## Commercial &amp; Legal Intelligence.

MACLAURIN AND CO., LTD. (photographic dealers, London).—Issue on July 31 of £200 4½ per cent. debentures, part of a series created January 1, 1906, to secure £2,000, charged on the company's undertaking and property, present and future. No trustees. Total amount previously issued of same series, £400.

ERNEST ELLIS, of 169, South Parade, Cleckheaton, who was made bankrupt in 1898 whilst carrying on the business of an artist and photographer, applied last week to his Honour Judge Bompas, K.C., at the Bradford County Court for his discharge. The Official Receiver (Mr. C. L. Atkinson) stated that a first and final dividend of 4s. in the £ was expected to be paid on proofs amounting to £90. The discharge was granted, subject to two years' suspension.

THE Purchase of a Business.—Mr. George Taylor, photographic artist, trading as A. and G. T. Taylor, 70, Queen Victoria Street, sued Mr. H. J. Blount, 63, London Road, Derby, also a photographic

artist, for £1 18s., money which the plaintiff alleged he had been compelled to pay. Mr. Aldous, solicitor, appeared for the plaintiff. It appeared that the defendant bought a photographic business from the plaintiff. By clause 8 of the agreement it was stipulated that the orders taken by the vendors during the last 12 months and the books uncompleted shall be taken over and executed by the plaintiff. The agreement containing that clause was signed by the defendant. Amongst the orders upon the books were certain photographs which were to be executed, and in respect of which sums had been paid on account. The purchaser, Mr. Blount, to complete those orders, thinking he would not get much out of the transactions. In consequence, the plaintiff was sued, and he sued the defendant. In one case the plaintiff was successful, another he was unsuccessful, for the reason that the plaintiff had not given notice to the defendant of the legal proceedings which were being instituted by a former customer. In the present case Mr. Gilbert gave an order for a picture, the price of which was two guineas. The defendant had the picture, but refused to pay for it. Mr. Gilbert alleged he had paid Taylor the whole price except a sum of 6s., and the defendant said the books showed that he was due of 12s. to be due. Mr. Gilbert brought an action against the defendant, and notice was given to the defendant on May 1. In consequence of that action the present claim was now made. Mr. Taylor, in evidence, said he had sent £1 15s. to the Court. It was several other cases which had been brought. On July 24 he went to the Registrar of the Burton-on-Trent County Court to see whether Mr. Gilbert had drawn any money from the plaintiff. The answer on the back of his letter was: "This action was discontinued in 1906. No money paid into Court." The defendant alleged the reason for the discontinuance of that action was that he had not the signature of Mr. Gilbert for the picture. Mr. Aldous said that it was proved that a mistake must have been made. He could not give judgment being given for the defendant. Judgment was accordingly, the defendant being allowed three guineas as costs.

THE Eastman Kodak Company of New Jersey.—The usual dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred Stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common Stock, have been declared payable on October 1, 1906, to the stockholders of record at the close of business on the 31st of September, 1906.

## News and Notes.

PHOTOGRAPHS of Scientific and Historical Paris.—The Paris Municipal Council have just announced that their annual competition for 1907 will be photographs of the Jardin des Plantes, the Luxemburg and Avenue de l'Observatoire, and houses outside Paris (Seine and Seine-et-Oise) over 100 years old. The historical buildings of the Jardin des Plantes (the residence of Cuvier, Buffon, etc.), and the facade of the Paris Superior School of Pharmacy is situated in the Avenue de l'Observatoire, will make this a particularly interesting competition. The public exhibitions of competing photographs will be held from May 15 to June 15, 1907.

THE Late Edward Telford Harrison.—The following is from the London papers of August 16:—"Edward Telford Harrison, Decedent.—Pursuant to Statute 22 and 23 Vic., c. 35. Notice is hereby given that all persons having claims against the Estate of Edward Telford Harrison, late of 127, Rue Lambrecht, Courbevoie (Seine), in France, Photographer, Deceased (who died on November 19, 1901), whose estate letters of administration, with the will annexed, granted by the Principal Probate Registry, on August 3, 1906, to Charles Mackintosh, the personal representative of Celeste A. Hamelin, Deceased, the residuary legatee therein named, are required to send particulars of their claims to us, the undersigned, the solicitor for the said administrator, on or before September 29, 1906, which date the said administrator will distribute the assets of the said deceased, having regard only to the claims of which he has then had notice, and that he will not be liable for the

any part thereof, so distributed to any person or persons of those claims he shall not then have had notice. Dated this 15th August, 1906. Stephenson, Harwood and Co., 31, Lombard Street, E.C., Solicitors for the said administrator."

**THE late J. H. Rawson.**—We regret to announce the death of Mr. James Harvey Rawson, of 11, Crescent Road, Sharrow, Sheffield, and a member of the firm of Rawson Brothers, cutlery manufacturers, Carver Street. When photography was in its infancy, and a few others started the Sheffield Photographic Society, of which for some years he was president.

**PRINTING from Stereoscopic Negatives.**—An interesting method of avoiding the transference of the prints from the stereoscopic negative is mentioned by M. Fabre in his "Traité Pratique," which we review on another page, and would seem to be a novel

Fig. 1.

Fig. 2.

means of printing at one operation from negatives which possess the correct separation. Assuming D and G (Fig. 1) to be the two negatives on the same plate, a piece of sensitive paper double the length of the whole negative is cut and folded, as in Fig. 2, the sensitive side of the paper being outside. A piece of black paper is placed between the two halves of the paper to prevent

Fig. 3.

the light passing through, and the negatives are printed from, first on one side then on the other of the folded strip. The paper is then cut, as shown in Fig. 3, and each piece mounted without further trouble. As we have said, the negative must possess the proper separation, and a further limit to the usefulness of the ingenious plan is that most emulsion papers will crack where folded. With albumen paper and others lightly coated, the device should be of service.

**THE Frahm apparatus** for frequency or speed measurement by means of resonance—either mechanically or electrically set up—with one or more of a series of vibrating tongues of known periodicity has now been in use for over two years, and has proved very satisfactory. Numerous attempts to make it a self-recording instrument have, moreover, failed, chiefly owing to the friction between the recording pen and the paper. This difficulty, says the "Electrical Engineer," has been overcome by making the record photographically.

**A NEWCASTLE Photographer Missing.**—Nothing further has been heard with regard to Mr. H. C. Deakin, photographer, of Newcastle-under-Lyme, whose clothes were found on Rhyl beach recently. The clothes were discovered placed neatly in a heap in a hollow of the sandhills to the east of the town, and appeared as if the owner had left them there while he bathed. A thorough search is being made for Mr. Deakin.

**DETECTIVE Photography.**—Photography was responsible for the capture of a bicycle thief in the Manchester district last week. Joseph Ferguson, alias Hill, 23 years of age, was committed to the Sessions on three separate charges of stealing bicycles. One was a motor-cycle, which, it is alleged, Ferguson endeavoured to sell to a cycle dealer. The dealer, however, had seen a photograph and description of a man "wanted" by the police for cycle stealing, and, thinking that he saw a striking resemblance, he made an

appointment with the man for the next day. Ferguson kept the appointment, but instead of a customer awaiting him he found himself confronted with two detectives.

**THE Royal Photographic Exhibition.**—Our readers should notice that the latest dates for exhibits to reach the secretary, in packing-cases, is Wednesday, September 5th. Pictures and other exhibits may be delivered by hand, unpacked, up to Thursday, September 6th, in each case to the New Gallery, 121, Regent Street, W. Entry forms for the exhibition are obtainable from the secretary, Mr. J. McIntosh, 66, Russell Square, London, W.C.

**THE R.P.S. One Man Shows.**—The next House Exhibition is announced for November 6th, when photographs by Mr. Henry W. Bennett will be arranged at Russell Square. The date of this exhibition will mark the reopening of the Society's premises after the alterations at present being undertaken, by which the present meeting room and council room will be thrown into one, and a single room thus obtained capable of accommodating a much larger audience.

**THE Traill Taylor Lecture.**—The ninth Memorial Lecture to the late Traill Taylor, for many years editor of the BRITISH JOURNAL OF PHOTOGRAPHY, will be delivered on October 23rd, at the New Gallery, Regent Street, W., by Mr. E. Walter Maunder, F.R.G.S., on "Photography in the Work of the Greenwich Observatory."

**ATTEMPTED Suicide.**—At the Portsmouth Police Court last week Jacques Gandle, a photographer, living at Oyster Street, Portsmouth, was charged on remand with having attempted suicide by throwing himself into the sea near the Clarence Pier. In his possession a letter was found in which the prisoner stated that he did not care if he was buried or cremated, and that he "died with a clear conscience and without fear." The Medical Officer of the Prison now reported that the man was of sound mind and suffering from melancholia. The Bench handed the prisoner over to a relieving officer.

**MR. HORSBURGH**, photographer, West Maitland Street, Edinburgh, attended at Drummond Castle on Saturday, when he had the honour of sittings from their Majesties the King and Queen of Spain, the Earl and Countess of Ancaster, and shooting party.

**ADDRESS Wanted.**—A correspondent, Mr. S. Wells, 23, Market Place, Richmond, Yorks, asks for the address of the Sciopicon Company, whom he has addressed unsuccessfully at 10, Highbury Quadrant, London, N.

**OZOBROME.**—This curious word (writes Mr. Chapman Jones in "Knowledge") is derived from "ozone" and "bromine," though it indicates a process with which ozone has nothing to do, and bromine very little. It is a method recently patented by Mr. Thomas Manly (who, a few years ago, introduced the ozotype process), by which a bromide print is made to furnish one or several carbon prints. This means that the facility of making a bromide print either by contact or enlarging methods, necessitating only a few seconds' exposure to artificial light, may be combined with the advantages of carbon or pigment prints, with their permanency and the wide choice of colours that they permit. Indeed, the new method presents notable advantages as compared with the ordinary carbon process, for not only is daylight unnecessary for the exposure, but the print is not laterally reversed, though there is no double transfer, and in one modification no transfer at all. The process seems, on the face of it, to have so much to commend it that the essential difference between it and carbon printing by the ordinary methods must not be lost sight of. Carbon printing, as hitherto practised, is a printing-out process, and the charm of a carbon transparency, as well as its reliability for reproduction purposes, lies largely in this fact. Probably no method gives a more exact representation of the negative, for the possibilities of altering the gradation by accident or design are hardly worth consideration. But in the "ozobrome" methods, the result depends upon development in the same sense in which the negative is developed, and while this may sometimes be an advantage to the skilled worker, it renders all sorts of errors possible. This radical difference must ever be borne in mind.

## Correspondence.

- *We do not undertake responsibility for the opinions expressed by our correspondents.*

### PROCESSES AT THE ROYAL.

To the Editors.

Gentlemen,—May I be allowed to make a suggestion with regard to the forthcoming exhibition of the Royal Photographic Society? It is that the processes by which the pictures are made should be mentioned in the catalogue. If this were done it would, I think, give increased interest to the show. I am an amateur, but with somewhat limited experience, and last year I was quite unable to distinguish the different processes by which the pictures were produced. If the Council of the society could see their way to do this, I think it would be of general interest to the visitors who, like myself, are not really experts in photography.—Yours, etc., C. A. MASON.

[We refer to our correspondent's letter under "Ex Cathedra."—Eds. B.J.P.]

### REMOVING YELLOW STAIN.

To the Editors.

Gentlemen,—I have noticed occasionally, in your "Answers to Correspondents" columns, replies to queries as to best method for removal of yellow stains in negatives, and was rather surprised to see that you consider there is no satisfactory means of overcoming the difficulty.

We are not particularly concerned with the cause (which is generally imperfect washing), but I do not think it would be outside the subject to make this remark in your reply. However, I have had occasion to use the following solution, and, although it is slow, I have found it serve the purpose admirably. I claim no originality whatsoever, having first seen the preparation recommended for stains in bromide prints.

Thiocarbamid .....	20.0
Acid citric .....	10.0
Water .....	1000.0

Plates to be immersed until clear.

—I remain, dear Sirs, yours faithfully, J. McRELTY,  
Proprietor, the British Dispensary.  
New Road, opposite Custom House Lane, Bangkok, Siam.  
July 11, 1906.

### NOTES FROM RUSSIA ON ARTICLES IN THE "B.J."

To the Editors.

Gentlemen,—Re testing prints on self-toning papers, I have repeatedly found, in testing coloured papers and colours for fading properties, that the colours under test fade sooner when air has free access to them than when pressed in contact with the protecting cover in a printing frame.

When engaged in factorial development, how would it be for the operator to don spectacles of red glass upon quitting the dark room, so that upon re-entering the red illumination would remain about the same?

As regards the Greenwich Observatory, many years ago (forty or more), when the Baltic railway was laid, a branch line to Pulkowa was almost finished, but as it was shown that the vibration caused would most likely interfere with the researches at the observatory, the company was ordered to abandon the branch. The embankment, overgrown with grass, remains to this day. Free England will, I

suppose, rather remove the Greenwich Observatory than cause an electric station to be destroyed.

As you will most likely hear more of Mr. Procoodin Gorsky (on "coo" and "Gor"), perhaps it would be better if his name were in English as I give it, being more approximate to the Russian pronunciation. I may mention that Mr. P. G. has been a co-worker with Dr. Miethe, and has considerably improved upon his method of taking negatives from nature for the three-colour process by running a large establishment here for half-tone process by which enables him to spend money on three-colour research. St. Petersburg. C. T.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I have read the letters of "A Disgusted Assistant" and "A Disgusted Employer." There are always two sides to a story, and as I have been both an assistant and an employer (had happy men and women to work in unison), perhaps you will allow me to add my contribution to the discussion. An old miller remarked to me, "When I engage a new man I let him have his own way the first few days, and if I notice his way is better than mine I take advantage of it. If not, I say to him, 'I want the sacks emptied or lifted or arranged like this,' and I let him my method." Now, reading "Disgusted Employer's" letter appears to let his workpeople have their own way, to his detriment. Let our friend show his new hands how he likes and intend work to be done. They only work as they have been taught to teach them better, and all will be satisfactory, then their satisfaction will be increased to mutual satisfaction. ARCHER CLARKE

### COPYRIGHT IN SCULPTURE.

To the Editors.

Gentlemen,—A short time ago there was erected in this town a memorial statue to the men of a regiment who fought and fell in South Africa, and, with commendable promptness, our printer photographed it previous to the public unveiling, and it has been locally published and copies sold. For this display of enterprise we have received a letter from the artist, a H.R.H.A. of some repute threatening us with dire punishment and commanding us to discontinue further sales and withdraw any we have sold.

From the abstract of the Copyright Law, which we take from B.J. ALMANAC, and from your answers to various correspondents on the same subject lately, we take it we were quite within our rights to photograph it, and do as we please with the photograph, and, further, we have registered this photograph, and informed the artist (upon inquiry) that if he wishes to reproduce our photograph he must pay the usual fee in common with any other person.

We shall be pleased to have your opinion on this and our advice in the matter, as it will doubtless be interesting and instructive to a large number of your readers.—Yours, etc.

H. ALLISON AND CO.

Armagh. August 17, 1906.

[Sculpture enjoys protection under Copyright Law, to the extent that it is an infringement to produce any cast or mould of it, it is not an infringement to produce drawings or photographs of it. That this is an injustice to the sculptor we will not deny, the fact remains, and the artist whose work has been photographed by our correspondent is either ignorant of the law relating to copyright or chooses to assume ignorance of it. The Royal Commission on Copyright of 1878 reported that: "Upon the whole, we are disposed to think that every form of copy, whether by sculpture, modelling, photography, drawing, engraving, or otherwise, should be included in the protection of copyright. It might be provided that the copying of a scene in which a piece of sculpture happens to form an object should not be deemed an infringement, unless the sculpture should be the principal object, or unless the chief purpose of the picture should be to exhibit the sculpture." This suggestion twenty-eight years ago has not yet become law, and our correspondents therefore have the law with them in the case they have taken.—Eds. B.J.P.]

## Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

J. Greenway, 27, Abington Street, Northampton. *Photograph of Northants C.C. and West Indians C.C.—Combined group. Photograph of the West Indian Cricket Team.*

USE ASSESSMENT.—I am writing to ask your opinion on the question of paying a rate lately put on my studio. About seven years ago I took to a studio, my late predecessor having had it sixteen years. I bought the studio as it stands, but have paid £8 per year for the land it stands on. Ten months ago I took another shop and studio in a more prominent position, and after getting settled went to see the landlord of the piece of land and he agreed to let me have it in future at £4 per year, as I now only use the old studio as a store place and for picture frame making. I had always paid the rates, it being assessed at £2 5s. all the years I paid the £8 rent, but as soon as my rent was dropped to £4 the rates were raised, it being now assessed at £6. I do not pay them through my landlord, but direct. Now, what I want to know is, can they assess me at £6 when I only pay £4 per year for the land and the studio, my own? I have appealed against it, but have only got £1 taken off, thus making it assessed at £5 now. If they cannot make me pay, what course am I to take?—D. G.

All leases, with the erections thereon, are subject to assessment to the public rates, and are charged upon the best rent that can be obtained. A rent of £4 being paid for the land the studio is assumed to be worth £1, and the assessment appears reasonable. An appeal can be made to Quarter Sessions, but the expense would be enormous for so small a matter. The assessment hitherto has been much too low.

TRANSPARENT BLUE PAPER.—Some time ago Mr. C. C. Vevers, Leeds, advertised a new transparency blue paper. An order for the same has been returned by the Post Office, marked "Gone Away." Mr. Wray, the optician, thinks that Mr. Vevers is dead. I shall be glad to hear from any firm who can supply this paper by the quire, equal to that sold by Vevers.—A. C.

A semi-transparent fabric is supplied by Messrs. Reeves and Co., under the name of "Linaura." It is easily sensitised with

ferro-prussiate, and may meet our correspondent's requirements. Messrs. Marion, with other firms, supply a thin sensitised linen.

CHEAP ENLARGEMENTS.—I should esteem it a great favour if you could kindly inform me as to the following: A firm had made me an offer to keep me busy all the year round if I could make them 20 x 16 enlargements, unfinished, at 8d. each, mounted. There are several firms that do this kind of work. What I want to know is, where I could get the bromide paper cheap enough to be able to get a reasonable profit. I have also to make a negative from photographs. Also which would be the best and cheapest way in working them?—N. D. M.

With the best intention of assisting our correspondents through the "Answers" column, we would suggest that you cannot expect us to assist you in cutting prices in this miserable way. You had better accept things as you find them, and see if you cannot turn out better work at something above such prices as you name. We doubt if such can be done, except with home-made bromide paper, or by the so-called solar process, of which we have several times given particulars.

REDUCER STAINS.—Will you kindly help me in the following? (1) I reduced some bromide prints, 10 x 8, with the ferri-hypo reducer, but when dried I found same all yellow stained. How can I remove this stain? (2) I left a plate developing (in a metol-quinol developer); a part of same accidentally got uncovered, and now this part is stained a chestnut brown. How can this stain be removed?—A. DAWSON.

(1) We very much fear there is no remedy, none which will leave the print good for anything. You may try a weak solution of ammonium sulphocyanide (5 grs. per oz. of water). A better reducer for bromide work is the iodine-cyanide, on page 960 of the ALMANAC. It will not stain. (2) We should advise you to bleach the negative with mercury chloride solution, and darken with soda sulphite, in which process perhaps the stain may disappear. Or you may try the bath recommended by a correspondent from Siam in another column this week.

THE RIGHT TO THE NEGATIVE.—Although I have seen your answer to the following question over and over again, is it asking you too much to confirm the following? A sitter comes into my studio for a dozen pictures. I give a receipt for same, without any mention of the negative. Whose right is invested in the negative? Can the sitter claim it in any shape or form?—F. R. O.

The negative is the photographer's, but to be used by him only at the direction of the sitter. See the article on page 675 in the ALMANAC.

COLOUR PHOTOGRAPHY.—You would greatly oblige me by recommending the most direct and least expensive method in colour photography. I have gathered, from occasional contributions which I have read in your paper, that it is not necessary to go to great expense. Unfortunately, I have not kept these back numbers, and shall esteem it a favour if you will put me on the right route, in order to attain proficiency in this branch of the science. I wish to deal with transparencies especially.—A. HERBERT.

For transparency work the most satisfactory process is the Sanger-Shepherd (Sanger-Shepherd and Co., Gray's Inn Passage, Holborn, London, W.C.); the same taking outfit will supply you with negatives for prints, which may be prepared by the carbon processes of the Autotype Company, or the Rotary Photographic Company, or by the Pinatype process (Fuerst Bros.), or by the imbibition process of Messrs. Sanger Shepherd and Co. We should advise you to get an elementary book on the subject, such as the recent "Natural Colour Photography," by König and Wall (Dawbarn and Ward, 2s.).

COLOUR PHOTOGRAPHY.—(1) In König and Wall's "Natural Colour Photography" (p. 76) I find it stated that a chromoscope, constructed from the directions of Professor Miethe, has been placed on the market by Birmopol, of Berlin. Can you tell me if this

instrument is to be had in England? If not, can you tell me of any one who would make one at a reasonable price, according to the detailed instructions given in the same book? (2) My three-colour negatives are all taken through Sanger-Shepherd's screens, and in many cases make excellent pictures by his "subtraction" process. Would these negatives be suitable for the production of transparencies for the chromoscope? (3) Would you give me your opinion on the following plans for transparencies? (4) The blue transparency to consist (as in Sanger-Shepherd's process) of an ordinary lantern slide, converted into blue, and the red and yellow transparencies, each on a separate glass, by the Pinatype process, and the three bound up together. It does not seem to me that the separation of the yellow image from the other two by the thickness of a lantern slide would make any material difference. If so, it seems a simpler plan to use that given in the Pinatype instruction book.—**COLOUR PHOTOGRAPHY.**

(1) So far as we know, it is not. Messrs. Sanger-Shepherd and Co., Gray's Inn Passage, London, W.C. (2) Yes. (3) In our experience in testing a somewhat similar method it is not possible to obtain a sufficiently sharp register of the three images.

**TONING BROMIDES.**—Would you kindly inform me of a good and quick toning bath for sepia bromides, one that will produce quite a cool sepia? The sulphide bath gives too warm a tone for what I require.—**R. A.**

The only other bath we can recommend you is the copper one—you will see the formula on page 979 of the *ALMANAC*—but we think it is possible you will get the cooler colour you want were you to try one or two other brands of paper. The colours with the sulphide process vary distinctly with the different commercial brands of paper.

**TONING P.O.P.**—I have seen some salts, with evidently a pinkish fluid poured over them, which, when dissolved, form a pink mixture, used as a toning and fixing bath for P.O.P. It gives a light or deep brown tone. Can you tell me where I can obtain a formula for same? It is very cheap, I believe.—**K. R. W.**

We cannot identify the salts from your description. Salts of a pink colour, such as those of manganese or cobalt, are not usually included in toning baths. If you can send us a sample of the substance we might be able to help you. But if the mixture is so cheap that it cannot contain gold we advise you to avoid it altogether.

**STAINED BROMIDES.**—Can you please give me a reliable formula for removing yellowness from under-exposed bromide prints (caused by forcing), (amidol developer)?—**TROOPER.**

See reply to A. Dawson.

**DAMAGED NEGATIVE.**—I have rather a valuable negative, taken about eighteen months ago— $6\frac{1}{2} \times 4\frac{3}{8}$ , dry plate, varnished—the film of which is coming away from the glass. Would you be good enough to inform me, through your "Answers to Correspondents" column, the best way of dealing with the plate, in order to preserve it from further injury?—**PUZZLED.**

Before attempting to do anything with the negative we should advise you to make a transparency from it, so that the negative can be reproduced if necessary. Place the negative in a dish of strong methylated spirit, to soak for half an hour or so, to dissolve off the varnish. The solution of it may be aided by gently rubbing it over with a flat camel-hair brush. Then rinse in one or two lots of fresh spirit to ensure the entire removal of the varnish and allow to dry. Then put the plate in cold water, and the film will probably leave the glass, when it can be floated on to a fresh plate. If the film expands unduly it can be brought back to its original dimensions by immersing it in spirit. The cause of the negative behaving as it has is that the film was not free from hypo when it was varnished.

**WATER SUPPLY.**—I have just received from the corporation of this town a notice to be filled in, asking that a water meter might be fixed to my supply, for which I have to pay about 6s. or 7s. per quarter. As I do not require their water for photographic purposes, but am supplied with rain-water from large tanks, can they compel me to have meter? Your advice will greatly oblige.—**PUZZLED.**

As you have a water supply to the premises, and employ water in your business, which, necessarily, requires a good quantity, we expect the corporation will compel you to have a meter. You will, we imagine, find it difficult to connect the corporation that you do not use water from the house in the business, and that you get sufficient for that purpose from a rain-water tank. If, however, you never use the corporation water in the business, and you have the meter, you will probably find your water bill less than it is at present.

**MERCURY TONING.**—Could you kindly give me, through the medium of B.J., a reliable mercury toning formula for bromide prints and postcards?—**SEASIDE.**

You can use a bleaching solution of a mercuric chloride, half an ounce, in a pint of water, and after washing the prints, darken them in fresh hypo solution, four ounces to the gallon. But why should you prefer a mercury process (which is of doubtful permanence) to the sulphide or copper methods, which are reliable?

**TONING P.O.P.**—(1) Is there any remedy for over-toning in the combined bath? When young hands are put to the work during a busy season they so frequently carry too far, and spoil the prints by accumulating. (2) What toning process would you recommend for prints very much over-printed? (3) Is there any remedy for yellowed postcards, toned in the combined bath? Some stand months and others seem to go in a few days, especially those toned in very hot weather.—**SEASIDE.**

(1) There is no remedy that we can say is of any value for over-toned prints, and the only preventive we can suggest is in using the bath. You may transfer the prints to a bath of soda sulphide, which will prevent the toning action continuing after removal from the combined bath. (2) It will be best to tone after fixing in a plain hypo bath, in which the prints will reduce more than when treated in the usual combined bath. They may then be toned in the combined bath or in the sepia baths—in the latter case after well washing. A very good remedy for over-printed proofs, and one which can be used after toning is made by adding five ounces of 10 per cent. solution of sodium in sulphocyanide, and half an ounce of 10 per cent. solution of potass ferricyanide to 24 ounces of water. The reducer will not spoil the tone. It may be used weaker or stronger than here given, according to requirements. (3) We think complete fixation and washing is the secret of avoiding the trouble. You must recollect that the thickness of the cards obstructs rapid penetration of the hypo and of the wash water. Attention is needed to keep the cards moving in the fixing and to see that they are thoroughly washed.

**THE Photographic Salon.**—We would remind our readers that Monday, September 3rd, is the receiving day for the Photographic Salon, on which date all pictures must be delivered at the Gallery, 5a, Pall Mall East, either personally or through an agent. The Salon opens on September 14th. The secretary, Mr. Reginald Craigie, will be happy to send entry forms to those applying to the Blenheim Club, St. James' Square, London, S.W.

**\* \* \* NOTICE TO ADVERTISERS.**—Books and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Tanqueray is prosecuting his free portrait frauds in the Argentine according to a correspondent, who communicates particulars of its latest form taken by the circular from Paris. (P. 698.)

An exhibition of portraiture by the late Mrs. Julia Cameron and H. Hay Cameron opens at the offices of THE BRITISH JOURNAL OF PHOTOGRAPHY to-day (Friday), and will remain open until October 6. Admission is free daily from 10.30 to 4.30 (Saturdays, 10.30 to 12.30). (P. 685.)

The present Cameron exhibition will be followed, on October 11, by one of portraiture brought together by the Professional Photographers' Association. Each exhibitor will send one print only, and all sent in will be shown; there will be no selection. Members of the P.P.A. intending to send in should advise the Secretary at 89, Albany Street, London, N.W. (P. 683.)

An American photographer, I. Benjamin, of Cincinnati, has established himself in Paris. (P. 688.)

The rights of a photographer in dealing with retouchers, enlargers, and others to whom negatives may be entrusted, are the subject of note on page 683.

In posing stout people, an American photographer reports his satisfaction with the plan of allowing the sitter to lean slightly over the back of a chair. (P. 692.)

In showing his various grades of work, the photographer should begin with the most expensive the customer will look at, and be slow to offer the cheapest. In asking for payment at the sitting and in charging for proofs, in the event of the sitter declining the photographs, he may take a firm yet courteous course. Some notes on these topics are taken from an article by Dundas Todd, in the "Photo Beacon." (P. 686.)

In arranging his window, the photographer should study colour schemes based either on contrast or harmony, and should endeavour also to provide a constant variety of subjects likely to prove of public interest. These and related matters are discussed in an article on page 683.

## EX CATHEDRA.

### Photographic Obstruction on the River.

A recent issue of the "Standard" devotes nearly a column to the nuisances which impede the practice of the Harvard and Cambridge crews for their coming contest on the Thames. Of these, says the "Standard," "The 'camera fiend' has probably been the cause of much of the trouble. He is beginning, in fact, to become nearly as much of a nuisance on the river as he has lately been in the Divorce Court, and it is unfortunate that there is no authority on the river which can eject him as summarily as Sir Gorell Barnes has done. In one case the Harvard crew were pulled up dead by a man in a punt who was so intent upon taking a snapshot of the eight as it passed that he paid no heed to the direction in which his boat was drifting." Our contemporary proceeds to take a somewhat gloomy view of the modern journalistic enterprises when it saddles the illustrated papers with the blame of creating the craze for photographing every public event. But it will be news to most people to learn that snapshotters have been a nuisance in the Divorce Court. Our recollection is that it was the artists and draughtsmen whom Mr. Justice Barnes drove from his court that his witnesses might not be embarrassed. The dim precincts of the Divorce and other Courts of Law can scarcely be described as a happy hunting ground for amateur photographers. However, we agree with our contemporary that if enthusiastic amateurs or those working for the illustrated papers impede the practice of the two crews on the river in the way they are said to have done there should be some means of putting a stop to the nuisance, if only for the credit of English sport—and photography.

\* \* \*

### Street Photography.

In street photography one of the greatest nuisances that the photographer has to contend with is the people who will persist in posing themselves in front of the camera. Many are the dodges resorted to to get over this trouble, and yet many picture postcards of street scenes that we see in the shop windows are considerably marred by having a group of street urchins in the foreground, or perhaps by one or two of the shopkeepers standing outside their shops with their arms akimbo, all anxious to appear in the pictures. More use in this connection might be made, we think, of working with the reversing mirror or prism, as is done in the majority of process establishments. The mirror or prism box being attached to the lens, a dummy lens is in turn attached to it, and the camera pointed across the street, when in reality the exposure is being made down the line of the thoroughfare. This device has been used with much success in hand-camera work—the late Mr. A. M. Geddiss, of Dublin, did some very good work with it—and it might

afford a valuable occasional aid to the touring landscape photographer. The drawback to the method is, of course, that it gives a negative reversed as regards right and left. While this may be an advantage if the pictures are intended for reproduction by, say, the collotype process, it is only an inconvenience when the printing is to be done direct from the original negative; but as it is usually the practice to make reproduced negatives for printing from, there is not much objection to the mirror on this account. In any event a non-reversed negative may be obtained by exposing the plate glass side to the lens, with the precautions, of course, that the glass is clean, and that an allowance of one-sixteenth of an inch is made in focussing.

\* \* \*

### Fortifications and Photographers.

On more than one occasion of late we have cautioned photographic tourists of the inconveniences they may bring upon themselves by their ignorance of the fact that the taking of photographs of fortifications—of which there are so many around our coasts—is not allowed. Many who are fully alive to the restrictions in foreign countries seem to be unaware that the same conditions prevail in this country, and that the regulations are now being more rigorously enforced. Since we last referred to the subject another case has come to public notice. A foreigner was observed by a sergeant of the Royal Garrison Artillery, who are dismantling the fortifications of the Scilly Isles, in the act of taking photographs of the Artillery's appliances. He was forthwith deprived of his camera, and the films exposed to light, so that they were spoilt. The man could speak but little English, and after being searched was allowed to go free. The sergeant's method of dealing with this case was certainly effective, though somewhat drastic, inasmuch as the exposures may not all have been on the appliances of warfare. In this case the photographer does not appear to have been long detained, but in other instances the supposed delinquents have been taken to the police station for the examination of the plates, at the loss to the tourist of some considerable portion of his holiday outing. We may be excused for again directing attention to this matter, but we are in hopes that the inconvenience to which the photographic tourist unwittingly exposes himself will not be disregarded.

### Bleaching Solutions.

So many after-operations depend upon a preliminary so-called "bleaching" of the image, that any information with regard to the action of different solutions is of great practical interest. In the extract from Dr. E. Sedlacek's work on toning bromide prints, which we published on August 17, there are several statements on the action of bleaching solutions that are worth note, and also some that we feel bound to criticise. A most important statement is that "it is essential to differentiate between pure halogenising mixtures and those in which oxidation first takes place with subsequent halogenisation." It is most important to differentiate between these two classes of bleaching solutions, because it is commonly assumed that the final results are the same, which assumption is quite contrary to fact. Pure halogenising solutions, such as chlorine water, bromine water, or a solution of iodine in potassium iodide, give pure chloride, bromide, or iodine of silver, which is undevelopable without exposure to light. On the other hand, solutions such as potassium bichromate, copper chloride, potassium ferricyanide, and potassium bromide, etc., give silver compounds that are readily developable without any

exposure to light, and that are probably akin to O. Lea's "photosalts." Moreover, the results have proved in many cases to be impure silver compounds, or, rather, admixtures of silver compounds with other compounds derived from the bleaching solution. The most notable example is potassium bichromate and hydrochloric acid, which gives a silver "photochloride" and a chromic compound. The conditions that govern the production of these "photo" compounds are not by any means understood, but, from work we have done ourselves, appears to be dependent on the quantity of free halogen available. If chlorine alone is present, as in chlorine water, pure undevelopable silver chloride is produced; no free chlorine is present a photochloride is formed. In respect to the bleaching power of a solution of iodine potassium iodide we distinctly differ from Dr. Sedlacek. So far from considering its action to be so slow as to render it almost useless, we should class it as extremely powerful and rapid. Much depends on the strength of solution, but one per cent. of iodine in a two per cent. solution of iodide is practically instantaneous in its action.

\* \* \*

### Potassium Bichromate and Hydrochloric Acid.

Some of Dr. Sedlacek's remarks in reference to this solution we are obliged to criticise. In the first place he states that it contains no free chlorine, free chromic acid. A fresh solution, however, undoubtedly contains free chlorine, and in considerable quantity if an excess of acid is present, while we are disposed to think that the existence of free chromic acid is somewhat doubtful. The most important constituent of the solution appears to be potassium chlorochromate, and a simple solution of this compound will behave in just the same way as the mixture of bichromate and hydrochloric acid. We have never noticed any tendency on the part of this mixture of bichromate and hydrochloric acid to reduce (i.e., dissolve) the silver image, allowed to act for a long time it will, however, dissolve away the chromium compound which exists in the bleached image, and possibly this effect has given rise to the belief that the solution is a solvent for silver.

### Business Lodestones.

A correspondent who writes us in appreciation of the notes on the commercial side of the photographer's business which have appeared in our columns of late, confesses that the value of good appearance in the get-up of an establishment, from the arrangement of the window down to details of stationery, has not impressed him with such emphasis when recently he had occasion to make a couple of domestic purchases—some bookshelves and a closed stove. The former he first selected from the catalogue of the manufacturers, and was led to favour a particular firm from the fact, which he recognised at the time, that the price list was elegantly produced with attractive halftones printed on fine art paper. In comparison with the lists of other firms the goods looked better, and inspection showed that expectation was justified of the catalogue and the goods were actually superior. The rule may not always hold good, but we think it will in the majority of cases. Usually the firm which understands how to produce a good article also realises the value of a good means of offering it to its customers, and such a means is a catalogue undoubtedly is. In the case of the stove, our friend recalled the fact of having seen a shop window in the City of London with three or four such stoves installed

and burning, and particulars of their cost and heating value prominently displayed. That window display had made a lasting impression on his mind, and he was led to seek the establishment as a purchaser. The introspective habit of our friend might be copied by photographers desirous of placing their wares before their customers in such a way that the inducement to purchase is a strong one. By analysing the methods of firms from whom he himself purchases, the photographer may expect to learn a good deal which he can copy, with variations, in his own business.

\* \* \*

**Pictorial Schismatics.** The correspondents of a weekly contemporary continue to be much exercised upon the questions raised by an artist in a lecture recently delivered at Russell Square. These questions are by no means new ones. They have been bones of contention for years. Lecturers and writers have dealt with them until one would think there is positively nothing else to say about them. The claims of detail, the sins of fuzziness and flatness are nevertheless once more provoking earnest and vituperative correspondence. The fact is difficult to understand unless we surmise that the charming and witty style of the last exposition has supplied an attractive gloss to a threadbare fabric. Photography of the pictorial sort is always between three points of attack. There is the artist, who appears, as a rule, to advocate clean, unmanipulated prints from sharp negatives; there is the artistic photographer, who will have none of that sort of setting-back from picture painters, but who continues to assert the "art" of his craft by making bids for qualities that belong to the graphic arts; further, there is the straightforward photographer of the old school who cannot break away from tradition, together with the amateur amateur, who scorns the artistic photographer's tricks because so far he is green in the business. These three classes are at loggerheads, and it is to be presumed that they always will be.

\* \* \*

**Their House in Order.** If there is a way by which agreement may be approached between these factions it will probably be found in the simple course of allowing merit of any sort to be its own reward. The banal practice of medalling is undoubtedly much to blame for angry divisions in the camp. To award a medal is to sow a crop of grievances, for that distinction is the unpardonable one. Praise from the Press, or purchase from the walls, is nothing by comparison. And, indeed, it must be admitted that a medalled picture, flaunting the greatness thrust upon it throughout the whole course of an exhibition, is an aggressive thing, to say the least. The custom causes a premium to be put upon any peculiarities the work may show; it gives rise to fashion-mongering; the success it implies inspires the vainglorious; and, lastly, when by chance the honour is misplaced the fact is highly lamentable. The excesses and affection of the too "arty" amateur would not flourish and survive were they not condoned by judges who occasionally mistake their ecstasies for criticism. Were each picture to run its fair course for fame, without applied distinctions, there would be an end to the whispering knots of dissatisfied aspirants which are now common objects of our galleries. Moreover, the mere imitator, who is after all the real culprit, would be considerably discouraged for lack of popularised patterns.

### The Exhibition Season.

Within a week or two the "Salon" and "Royal" exhibitions will be open, and the photographic exhibition season may then be said to be in full swing. During the next two months visits to London will be paid by many of those in the country interested in photography, and we may therefore draw attention to the little exhibition of the work of Mrs. Julia Cameron, which opens at our office to-day, and to the one which on October 11th will replace it. Mrs. Cameron's photographic portraiture, done nearly fifty years ago, is often referred to as anticipatory in its aims and character of much which is put forward as advanced work at the present time, and we are therefore right in assuming that many will be glad to have the opportunity of inspecting a collection of about forty examples which have been brought together by the courtesy of Mrs. Cameron's son, Mr. H. H. Hay Cameron, and the Auto-type Company, who are publishing carbon prints from a number of Mrs. Cameron's negatives.

\* \* \*

### A Single Picture Exhibition.

From October 11 to November 10 the little gallery at these offices is to house a collection of examples of portraiture by members of the Professional Photographers' Association. The exhibition consists of single examples typical of the work produced by each exhibitor in the course of his business. Each exhibitor will send one print, and there will be no selection. Every print sent in will be hung. It is hoped that as a result of this exhibition photographers in different towns will be afforded the opportunity of inspecting what they cannot see elsewhere, namely, specimens of the work which their brother professionals in other towns are producing for sale to the public. The "single-picture exhibition" which was arranged on these lines in America last year was a source of very great profit and interest to those assembled at the convention of the New York Society of Professional Photographers, and it is hoped that members of the P.P.A. will be no less enthusiastic in making a collection representing the present position of professional photographers in this country.

\* \* \*

### Retouching Disputes.

The photographer's right to his negative is a form of proprietorship which is apt to be regarded too lightly by those having dealings with the photographer. It is not uncommon to hear of cases where a retoucher or enlarger who works for the profession has had negatives entrusted to him on which he has, for example, done a certain amount of retouching. Where such a business is done on a "cash before delivery" basis, instances have come before our notice of the retoucher refusing to deliver the negatives until his bill has been paid. It is scarcely necessary to say that he cannot legally take such a high-handed course. The photographer can enforce the return of his negative and the retoucher can sue the photographer for the money; or, if he will not part with his labour until he has been paid for it, he can clean off the retouching and deliver the negative to his customer in the state in which it was sent to him. Similarly in the case of enlargements, a firm doing work of this kind has no right to retain negatives entrusted to them pending payment of, say, a former account. Instances where such action has been taken occasionally come to our notice, but there is a remedy which usually proves effective, and that is for the photographer unable to recover his property to drop a note to the superintendent of police in the district, who will generally take steps to remind the delinquents of their responsibilities.

## THE PHOTOGRAPHER'S WINDOW.

## II.

IN our former article we entered at some length into the construction of the shop-window, and expressed a hope that we should be enabled to say more about the actual arrangement of the specimens at some future time. As a fulfilment of this wish we, in this paper, intend to confine ourselves to that subject. It may be said at the very outset that most windows suffer, as, indeed, may be said of many exhibitions, from the fact that the specimens are overcrowded. A small, select, frequently changed show, with sufficient space to isolate without making the items appear solitary, is much the best policy, and far preferable to a large, chaotic and crowded display.

The work shown at one time should be of a fairly harmonious description. That is to say, should not be composed of too varying or contrasting pictures—say, red carbons, weak plats., and weaker oils jumbled up cheek by jowl. We do not mean that all the work should be absolutely of the same tone, or that coloured work is to be barred—but discretion must be exercised.

On the bottom may be placed a few cabinets, panels, etc., on struts, never lying flat on their backs. Next may come a few more important works, raised slightly, and then, above all, one or two big enlargements on easels. But do not always try to make the back pictures rise high, and, above all, do not raise them in well-defined steps. Avoid all appearance of showing after a pattern; a studied carelessness is much better. The great point is care in placing the prints so that they are not killed, or do not kill other prints in near proximity. A few small cabinets only we think advisable on the floor, and they may reasonably be examples of the different styles done; but, beyond once more warning against overcrowding, we would leave the general arrangement of a window to be decided according to circumstances.

There is another view of window displays, however, that is exploited by one or two of the best men, and that is specialisation, and, if the work done at a gallery is varied enough, there can be no better way of making a display, for it will be found that in all matters of art a scheme in harmony is much more easy to manage and bring to a successful consummation than a contrasting one, though it may be said these latter methods, when successful, are much more striking than the former.

To elaborate a little it will be as well to give a short description of how this specialisation is carried through, leaving the reader, of course, to devise other schemes for his requirements.

The first show, then, may be carbon prints—say, in tones of brown with perhaps a red chalk here and there to relieve the monotony, for repetition without variety is bad art. In this case the curtains behind would be dark brown, if the scheme were entirely in harmony, or dark green if a note of contrast is to be added; usually if the mounts are brown and prints also the curtains are green, and some of the frames are green; whilst if the mounts are green the background is brown, although this is really of no importance, the only point gained being that the prints stand off from instead of being part of the background when viewed from a short distance. In one of the best shows we have seen the scheme was in brown against old gold (a sort of brown) hangings. The small prints in brown, then, should be as varied in subject as possible, and a few prints in the Cosway and other fancy masks included. Also a folder or two in harmonising colour might be inserted. The larger pictures will, of course, be framed, and should be in a

quiet brown or green wood frames, and on no account gilt, which will clash and throw the whole show out.

There should be at least two or three enlargements about 24 by 18 in the background to pull things together, for collection of all small work looks niggly and irritates onlooker.

Another scheme may be all platinotypes and blue prints against a dark grey or black background, with perhaps two or three small warm-toned prints to throw them up, but be sure they are not aggressively warm-toned or they will merely attract attention to themselves.

In one very successful show that was most distinct the window was draped in dove grey. All the prints were of a sketchy-light order against white backgrounds, and mounted on large rough white paper and light grey mounts. In the background were two black and white drawings, also in sketchy style. The whole was most striking, and successfully pushed a new line of work for ladies and children.

But these examples will suffice; harmony is the prevailing note, but a few hints on specialisation in other directions will not be amiss. A show of men only is bound to create attention, because "it is different," and if you get a window of local celebrities—councillors, and what not—the point is enhanced tenfold.

A window of children only will exploit this branch of your work as no other means of publicity could; so will a window of groups—ladies, and any other style you make. They make an impression because "it is different," and because they appeal by themselves, there being other styles to distract the attention and leave a mere muddle of ideas in place of one distinct and good impression.

Then again, some photographers make a good hit showing photographs of local interest. The local football team with the new cup, the newly-elected mayor, church constable, or other worthies. The characters in the "swell" dramatic performance, or the attendance at the mayoral fancy dress ball, or the group of a wedding party.

Then there are certain local happenings that depend for their force on quickness of production. If you get a photograph of a fire, sewer burst, scene of a street accident, or anything of that sort, and get it in your window within twenty-four hours, you get talked about. We recall the case of a photographer in the North, who resided in a seashore town, made great capital when the local pier was washed away in the night, and his postcards were selling 10.30 a.m., and a big enlargement was exhibited in his window at 12 o'clock.

Of course, such opportunities do not often arrive, but there is another point which can be taken advantage of, and that is to have what one might call topical shows. If you are in a garrison town you will probably take many men in uniform. If in a hunting centre photographs of ladies and gentlemen on and off horseback in hunting costume will appeal to the locality. For even your clients do not wish to be taken in, or do not possess uniforms or special costumes, they are familiar with them and it is a safe card to let the public have photographs of things they understand.

An "Ex Cathedra" note recently remarked that specimens would make a stronger appeal and be more attractive if the costume was appropriate to the weather. This indeed, cannot be gainsaid, for a shiver mentally runs down one's back when looking at a portrait of a lady in outdoor summer costume whilst the ground is covered with snow. Of course, evening and indoor attire generally is pretty similar winter and summer, and may be exhibited all the year round, but the caution re outdoor costume is worth attending to.

A photographer recently revived the old idea of taking

people apparently in a snowstorm, and his window attracted much attention. The effect is easily obtained with a brush and colour on the glass side of the negative. The actual falling effect is obtained by dipping an old and soft toothbrush in liquid crimson lake, shaking out superfluous liquid, and then holding the brush about six inches above the negative and tapping it sharply with a pencil or other similar object.

A strikingly inappropriate show, however, sometimes attracts more attention than an ordinary conventional one would. The above snow pictures exhibited in June would create a mild sensation, and this is not to be despised.

But the show must be obviously inappropriate, and not slightly so, or the effect may be put down to carelessness.

In connection with the above, we might cite an instance of a large firm of textile merchants of Bradford, who, in the month of August, 1902, a year that may well be remembered as being extraordinarily cold, wet, and inclement, made an exhibition in their windows of furs only. One never looks at shops of this description as a rule (except when with female relations), but this show, so inappropriate in one way, and yet so apt in another, made us pause, and thus notice a shop that had never before made any sort of impression upon us.

## PHOTOGRAPHS—ANCIENT AND MODERN.

THE exhibition, which opens to-day in the little gallery at the offices of the BRITISH JOURNAL OF PHOTOGRAPHY, should prove interesting to the many who, for pleasure or profit, employ the camera for portraiture. There are few, we suppose, who have not heard of the work of Mrs. Julia Cameron, though those who can recollect its appearance at the annual exhibitions of the Royal Photographic Societies years ago cannot number very many, and perhaps there are fewer still who, in their journeys upon the South Western Railway, have alighted at Brockenhurst in the New Forest and spent half an hour in examining a small collection of portraits by Mrs. Cameron, which hang in the waiting room. Though we have referred above to Mrs. Cameron's work as ancient, it is so only chronologically; in aim and character it belongs to the modern movement in photography, and many of the portraits in the collection now brought together might be instanced as possessing qualities which have been esteemed and extolled by those who, by act or precept, have joined in the revolt against the stereotyped professional portraiture of the "curtain, pillar, and vase" type, such as flourished almost universally in Mrs. Cameron's time and is not killed outright yet. Not long ago we drew prominence to the work of Major Puyo, of the Photo Club de Paris, in advancing the making of good portraits by the introduction of the so-called "anachromatic" lenses, the slight want of critical definition in which permitted the photographer to relieve his photograph of biting sharpness of delineation. Mrs. Cameron had no "anachromat," but she was accustomed to open out the stop of her single lens beyond the prescribed limit, in order to avail herself of the benefits of spherical aberration.

In other respects, the collection is interesting, for it includes portraits of men, such as Tennyson and Browning, made by Mrs. Cameron, and many years afterwards by her son, H. H. Hay Cameron. Mr. Cameron's fine series of portraits, including those of the present Archbishop of Canterbury, Henry Irving, and Lord Roberts, are fittingly shown with those of his mother, and will be seen to possess a variety which is scarcely seen in those of the latter. These, it should be stated, are all carbon prints, by the Autotype Company, and, though technically excellent, cannot claim to have any personal supervision in their production, such as a photographer of the class of Mrs. Cameron would certainly exert. The following is the list of the photographs:—

BY MRS. JULIA CAMERON.

1. Thomas Carlyle.
2. Lord Tennyson.
3. Sir John F. W. Herschel.
4. Longfellow.
5. Joachim.
6. Charles Darwin.

7. Thomas Carlyle.
8. Lord Tennyson.
9. G. F. Watts.
10. Robert Browning.
11. Zoe.
12. Three Fishers.
13. King Arthur.
14. Christobel.
15. Mary Mother.
16. Ophelia.
17. The Meeting of Sir Launcelot and Queen Genevieve.
18. Alethea.
19. Stella.
20. "Call, I follow, I follow, let me die."
21. The May-Queen.
22. Miss Ellen Terry (at the age of seventeen).
23. The Angel of the House.
24. The Angel in the Sepulchre.
25. Nestling Angel.
26. A Study.
27. The Passion Flower.
28. A Day Dream.
29. Sunrise.
30. Florence.
31. St. John the Baptist.
32. The Kiss of Peace.
33. A Child's Head.
34. Portrait of Mrs. Julia Cameron. (From a Painting by G. F. Watts.)

BY H. H. HAY CAMERON.

35. The Five Foolish Virgins.
36. The Archbishop of Canterbury.
37. Miss Bagge.
38. Miss Ramsay.
39. A Child's Head.
40. G. F. Watts.
41. Dr. Jackson.
42. Mrs. Stuart Wortley.
43. Master Jimmie Marshall.
44. Portrait of a Boy.
45. E. J. Levison, Esq.
46. Tennyson and Browning (bearing the poets' autographs).
47. Henry Irving as "Becket."
48. Miss Muriel Paget.
49. Lord Roberts.

The exhibition will remain open until October 6, from 10.30 to 4.30, except on Saturdays, when the hours are 10.30 to 12.30.

THE United Stereoscopic Society.—This Society's second annual competition of members' work will be held in November, 1906, when a bronze medal is offered for the best slide entered in each of the general classes. The secretary of the society is Mr. A. J. Snow, 74, Lloyd Road, Walthamstow, E.

West of England Exhibition.—In connection with the photographic classes in the above exhibition we are asked to say that the detailed schedule is now ready, and will be sent on receipt of a stamped foolscap envelope. The secretary's name and address are Mr. A. D. Breeze, 41, Union Street, Plymouth.

## BUSINESS TACTICS.

THE methods which photographers across the Atlantic have found efficacious in intensifying the volume of business and assisting to sell a more profitable article have found their way into our pages during the past few months, chiefly in the form of addresses read and discussed at the conferences and conventions which are so large a feature of photographic life in America. Most of these have come from professional men, proprietors of studios, who are speaking of things as they, individually, have found them. Of a different order, but no less useful, is an editorial in the current number of the "Photo-Beacon," in which F. Dundas Todd presents a kind of *pot-pourri* of the ways and means adopted in the States among professional photographers. Mr. Todd's article is good enough, it seems to us, to present practically unabridged.—ENDS. B.J.P.

"When a prospective customer steps into the reception room, the first sixty seconds is really the most important part of the interview, as in that brief minute the reception room lady or photographer must have created in her mind a pleasing impression, either learned from her directly or estimated by sizing up just how much money she is willing to pay and how much more she can be tempted to spend." Thus said a photographer to a meeting of his brother craftsmen recently, and almost all of them admitted there was much truth in his statement.

### Have your Place Spick and Span.

First impressions count for much, and are hard to obliterate even by opposite ones that are made later. Let me illustrate. If a lady were told that while arrayed in her best gown she would be asked to sit in a dusty chair while she was being photographed one might be reasonably certain she would never enter the studio where such conditions existed. Yet a travelling man told me recently that while waiting in a certain gallery, owned by a rather successful photographer in a large residence city, he overheard a lady sitter, handsomely arrayed, beg to be excused for a moment, saw her retire to the dressing room, then return under the skylight, carrying in her hand a towel. From the conversation, which he could not avoid hearing, it was plain the posing chair was dusty, and she was preparing to wipe it.

I have been in this photographic gallery and know the reception room is rather presentable, but I am convinced if the lady had seen dusty chairs in this room she would never have made the appointment. First impressions are important, more so than those that succeed, but the latter should not be neglected.

Anybody can sell a customer what is wanted, but the good business man endeavours to sell an article that is more profitable to him, at the same time retaining the customer's good will. We are all in business for profit, if we were not the awful avalanche of trash of all kinds that is sold every day in the year would never be produced, and it is sound business to make the biggest profit possible while conforming to the recognised rules of the game. If the customer is evidently a \$3 one then the photographer has to tempt her to spend at least \$1 more. Failing that, he must angle for 50 cents. And so on all along the line, no matter the prices.

### Two Guiding Rules.

Every man does his business more or less his own way, and it is utterly impossible to lay down hard and fast rules, but I find there is a general consensus of opinion on two points. First, no small pictures should appear on the walls of the reception room, or where they would be readily noticed. Only 8 by 10 or larger pictures should be displayed openly. Secondly, the regular line of work should be kept in drawers, or preferably in a display cabinet, such as is now offered. For those who have not seen one, I may say the cabinet contains about half a dozen frames, about 30 inches by 40 inches, which stand upright while in position. As each is lowered by a forward movement, the one behind becomes visible. This cabinet permits any one class of work to be shown together, and at the same time all prints are kept clean and free from dust. I hear it spoken of very highly wherever it is in use.

### Be Slow to Offer the Cheapest.

Some definite system must be followed in making or exhibiting the various grades of work that are made. There has long been quite

a contention as to whether the lowest priced or the most costly should be shown first, but I find most men agree that the expensive the customer will look at is a good place to begin.

Let us suppose a case. A customer is in the reception room the lady behind the desk has sized her up as a \$10 possibility—an effort. The door of the display cabinet is lowered, and customer's eyes are at once met with, say, three very large prints on heavy paper and unmounted. The customer will be almost certain to express an opinion of them and to ask the price. "Twenty dollars a dozen." If her intention is to pay about \$4 a dozen, she will almost involuntarily remark, "I don't want anything like that; something about \$4 is all I want to pay."

The photographer would be foolish to at once show his \$4 stuff. There is no need for hurry at the present juncture, and there while talking pleasantly about whatever may be interesting to the customer, he lowers the next frame, on which will probably be \$12 or \$15 pictures. If the customer expresses a desire to see cheaper priced work, the next frame is lowered, and so on, but the golden rule here is never go further back into the display case than must, and in the majority of cases a skillful salesman or saleswoman can add at least 50 per cent. to the sum the customer intended to spend.

### The Profitable Odd Lines.

Many photographers tell me that they consider the arrangement come to at this stage as being merely temporary, though the customer looks upon the styles as being definitely fixed upon. When the prices are returned this should be considered as a second opportunity inducing some variations that will add to the value of the order. We all know that such staple goods as unbleached cottons are sold at a fairly uniform price, and at a low margin of profit, simply because most customers have had experience in buying this class of goods but when we come to ladies' hats the customer is up against a very different proposition, and every husband is aware that a few flowers and ribbons arranged on a straw frame become very decidedly enhanced in value. It is a recognised fact in all businesses that big profits are to be got on the odd articles, so photographers ought to follow this lead, and therefore tempt their sitters with work that is outside of the regular cabinet style.

### The Question of Part Payment.

It is a recognised principle in business that all articles produced for personal use are paid for in advance, because they are consumed or at least material is consumed, in providing the service. For instance, we pay for a railway journey at the beginning of the trip and for a theatre performance before it starts. Photographs are under the same list, and ought therefore to be paid for in advance as the material and time cannot be recovered and put to other use should the customer refuse to pay. The principle of a deposit therefore is a sound one, but the application requires to be handled with considerable tact. In some studios one finds such a notice as this on the walls: "No sittings made without deposit of \$1." Many years ago in one gallery I dropped into I found the photographer had such a notice on a small stand in his operating room, and just when he was ready to make the exposure he pulled this into position and requested the poor sitter to look at the card. I fancy many of his customers felt anything but pleasant when this notice was suddenly presented to them at such a critical moment.

Coming back to the reception room and the question of part payment: It is sound business to get a deposit at the time of sitting, but many photographers think it unwise to ask for it until after the sitting, and then the question must be put very tactfully. Some men like one phrase, some another. For instance, one man will ask, "Do you wish to make a part payment on these now?" while another will prefer this question, "How much do you wish to pay now?" because this phrase makes it apparent that so much must be paid.

When I come to speak of handling a customer under the skylight, feel like saying "don't handle at all. Hands off" is a mighty good rule, and I find that first-class men never on any pretence touch the customer. Many people have decided objections to being touched. I speak with feeling here, as I happen to be built that way; and

would refuse to do business with any one if I knew I was going to be handled.

### Charging for Proofs.

The question of proofs has got to be a big problem these days, since the amateur is everywhere in the land, for it is no unusual thing for the customer to finish the proofs from which no order is given and thus get the benefit of different positions for nothing. As a consequence there is growing up a custom among photographers to stamp in the back of each proof some such statement as this: "Please mark your order on the proofs you wish finished and write your name; all proofs not returned will be charged for at the rate of finished prints." Some photographers are willing to make one toned unmounted proof from the negatives not ordered from to be mounted in the baby book, but even here one must use judgment, as one photographer tells me of one of his customers, who brought in her little boy one day, with seven different suits of clothes, and had him taken in two positions with each suit, then wanted only one

unmounted print from each negative at 25 cents. He faced the problem by informing her that this rule only held good provided one dozen was ordered from at least one negative.

"When will my pictures be ready?" is the usual question asked by the customer. Photographers have gained for themselves a rather unsavoury reputation for broken promises, and it is about time to reform. They should never promise for a definite date, but instead should offer to notify by dropping a postal when proofs are ready.

I am often asked the question, should the photographer urge the customer to take prints from the negative he thinks best or permit him to choose. In the first place, I will say that no photographer should ever submit a proof from a negative he would not like to finish from. From the others let the customer take her choice. She is paying for the service, and therefore has the option. When I want bacon and eggs for breakfast I would resent very emphatically the waiter's interference, if he urged me to take beefsteak instead, because it is my palate, not his, that is to be tickled.

## EXPERIMENTS WITH SILICIC ACID EMULSIONS.

(A Paper in the "Zeitschrift für Wissenschaftliche Photographie, Photophysik und Photochemie.")

Among the many unsolved problems of scientific photography are the nature of the latent image and the existence of solarization. Hitherto these phenomena have been chiefly studied in gelatine and collodion emulsions, but lately (1), on the supposition that the organic vehicle of the emulsion complicates the results, experiments have been undertaken with films free from such vehicle. These researches have led to one important conclusion among others—viz., that solarization is not, as has been assumed by some writers, dependent at all on the tanning of the gelatine, but arises from a special alteration of the silver bromide. Whether the composition of the surrounding atmosphere plays a part in the process, as it does in certain phenomenon of the latent image, is a matter to be settled by further experiments. It is known that a primary plate (i.e., one obtained immediately on exposure), after fixation, is developed by a developer containing silver, and that the image remaining after fixation is only incompletely or with great difficulty decomposed by nitric acid. Doubt has been often (2) expressed that this extremely permanent substance of the latent image consisted of an organic body. In order to put the matter to the test we have attempted to prepare an emulsion of silver bromide in an inert inorganic vehicle, and to make corresponding experiments under these conditions.

Encouraged by some work of the late C. A. Lobry de Bruyn (3), we carried out experiments with emulsion of silver bromide in silicic acid. De Bruyn, in the course of his work on the physical condition in water of bodies which jellyfy, prepared a silver bromide emulsion as added, and to the other 5 ccs. of N/10 potass bromide solution. On mixing the two mixtures, de Bruyn obtained a white emulsion which jellyfied in 2 to 3 minutes. It exceeded in sensitiveness a ripened gelatine emulsion. Our own repetition of this experiment gave the result that the setting of the silicic acid took place further than was desired, so that even by working very quickly the silver nitrate solution could not be added to the bromising solution in the proper time, as it was seldom possible to coat several plates with the same emulsion; a variation in the process appeared most advisable to us, especially as the emulsion prepared according to de Bruyn's directions contains large quantities of sodium nitrate which are removable with difficulty.

### Preparing the Emulsion.

We, therefore, proceeded to prepare the emulsion with colloidal silicic acid, purified as highly as possible by dialysis. As the solution which is deprived of electrolytes to the greatest extent sets very

quickly, we set out to prepare, first, a solution of only an approximate degree of purity, in the following manner:—30 ccs. of solution of sodium silicate (density, 1.3) and 30 ccs. of pure, strong hydrochloric acid, were each diluted with 120 ccs. of water, and the acid poured, while stirring, into the water-glass solution. The mixture was subjected, in two portions; for three days to dialysis in running water. As a dialysing vessel, a beaker with the bottom knocked out, was used, a piece of pig's bladder, cleaned with alcohol, closing the aperture. When dialysis has continued only so long that on addition of silver nitrate to the silicic acid solution only a weak opalescence is produced, the solution can be stored for several days without jellyfying. To prepare the emulsion, a portion of this stock solution is given some further dialysis until silver nitrate shows no opalescence. Such a solution is not even now free from electrolytes. Graham (4), it was who, in his classical researches on dialysis and diffusion, assumed that a perfectly pure silicic acid solution was obtainable, but E. Jordis (5) has, however, shown that a quantitative purification of the solution, or of the gel, is next to impossible. He takes the view that in the absence of "solution former" (i.e., of the electrolyte used in the preparation), no state of solution is possible. The way in which electrolytes favour solution was well-known to Graham, but in what way the almost infinitesimal proportions of electrolytes are retained by the silicic acid is a much debated point. While the old view was that of absorption or adsorption, Jordis assumes that the acid by virtue of its "amphoteric" character (simultaneous formation of H and OH ions) may cause both sodium and chlorine to combine chemically at the same time.

### The Emulsion Formula.

The preparation of the silver bromide emulsion was as follows:—

I.		II.	
Silicic acid sol.....	35 ccs.	Silicic acid sol.....	35 ccs.
10 p.c. potass bromide sol. 5 "		10 p.c. silver nitrate .....	25 "

Solution I. was added to solution II. from a dropping funnel with constant shaking. There was formed a very fine grained emulsion which was left standing for half-an-hour in the dark, was filtered through flannel, and then coated on to the plates. For a plate 9 x 12 cm., 10 ccs. was used. The filtration is necessary to remove any non-colloidal (coarse grained) particles of silver bromide which would fog in the developer not being protected by the film of gel.

The plates to be prepared were placed in light-tight boxes to permit of the slowly setting emulsion jellyfying in them without being moved. Almost pure silicic solution, stored for a long time, gelatinises most quickly on precipitation of the silver bromide. That freshly prepared, especially at a lower temperature, requires addition of ammonium carbonate. The setting is complete, on the average,

after four to six hours. The plates are then washed (to remove excess of potassium bromide) until the wash water is no longer rendered turbid on addition of silver nitrate.

On drying, the film partly leaves the glass: the defect is not remedied by a gelatine substratum. From the very brief details which de Bruyn gives it must be supposed that he was successful in working with the dry films. As the examination of dry films appeared very desirable, particularly from de Bruyn's statement that the sensitiveness, in the dry state, exceeded that of a ripened gelatine emulsion, we made a number of attempts to employ the dry film, but without success. We eventually decided on the plan of working with the washed and still wet films as sufficient for examining solarisation, and the formation of the latent image.

The opacity of the washed plates is less than that of most gelatine plates of medium sensitiveness. By transmitted light the films showed, as a rule, a blueish-white colour. On protracted exposure to daylight they became greyish-black.

If the emulsion is prepared by the silver oxide ammonia process, the emulsion darkens very quickly in daylight to a violet-black. We have not continued the experiments with this emulsion, as the presence of ammonia was not required for experiments, and, further, the ammonia greatly interferes with the setting of the solution.

#### Sensitometry of the Films.

The wet films were exposed in a tube sensitometer. As it was necessary, for many experiments, to obtain two plates with exactly equal exposures, we installed a double-tube sensitometer. Two metal plates were provided with sixteen circular holes, the sizes of the openings increasing in the ratio of  $1:\sqrt{2}$ , giving this for the sixteen areas, the following values in 89 mm. :—

181	.....	128	.....	90.5	.....	64.0
45.3	.....	32	.....	22.6	.....	16.0
11.3	.....	8	.....	5.7	.....	4.0
2.8	.....	2	.....	1.4	.....	1.0

The diameter of the separate holes was accurate to  $\pm .05$  mm., and it was found that corresponding openings did not differ by more than  $\pm .025$  mm. On the inner side of each plate sixteen tubes of matt black paper were fastened corresponding to the holes; they were fixed at their lower ends to a thin sheet of zinc in which sixteen large holes had been made. This arrangement is easily fixed to a light-tight metal-chamber and to the plate-holder.

In the first experiment a plate was exposed for the same time as a Hauff transparency plate which had been soaked in water for half-an-hour. The exposure was made to daylight through a window covered with several thicknesses of oil paper, and it was found that on three seconds' exposure the gelatine plate developed up to No. 14 of the holes; the silicic plate only to No. 3. The plates were laid on white paper and examined perpendicularly when making this comparison. As the area of No. 3 is forty-five times that of No. 14, the speed of the silicic plate may be put down at 1.45th that of the Hauff transparency plate.

As developer, the normal ferrous oxalate of Dr. Eder (6) was used with prolonged exposure, the silicic acid plate showing a tendency to fog, especially where the edges dried. As Lobry de Bruyn makes no mention of the way in which the plates were exposed in his experi-

ments, it is not impossible that the remarkably high sensitiveness found by him was really fogging of the dry film.

Under the microscope the silver bromide was visible as an extremely fine grain.

#### Solarisation.

The plates were exposed in the sensitometer for one hour at metre from the window covered with oiled paper. After eight minutes' development, the action of the developer was arrested; fog commenced to show itself. After fixing it was seen that areas Nos. 1 to 4 showed distinct reversal against the background, which was somewhat darkened by halation. Areas No. 5 and 6 were neutral; 7 and 12 were over-exposed, and 13 to 14 normally exposed. No. 16 was invisible. These results supply fresh proof that solarisation has nothing to do with the tanning of the vehicle of the emulsion, but is connected with a modification in the silver bromide. We have later ascertained that in the case of silicic emulsion, as in that of gelatine, solarisation is increased by previous treatment of the plate with oxidising solutions (7), such as nitric acid of 1.3 density, the action being partial or complete according to the time of action, so that it is possible to obtain normal negatives from plates which have been exposed up to the point of direct blackening.

#### Secondary Development and the Latent Image.

Plates exposed for one hour in the sensitometer at one metre distance from the window, were fixed immediately after exposure in 1.5 hypo solution. The photo-bromide formed disappeared completely. The plates were then washed for half-an-hour, and developed in metol developer containing silver nitrate.

After one-half to three-quarters of an hour traces of the image appeared; the development was complete after two hours, and it was then seen that areas 1 to 12 were blackened, the first four strongly. Some pairs of plates were now given equal exposures, one plate of each pair fixed directly, and the other after previous treatment with nitric acid. Both were afterwards developed. Between fixation and the acid bath the plates must be thoroughly washed for 2 or 3 hours, since any residual traces of thiosulphate will be decomposed and appear as sulphur in the film. After two hours' secondary development the following results were obtained:—

Plate without acid treatment.....	11 areas.
Plate with 1 hour in nitric acid (1.2).....	9 areas.
Plate with 1 hour in nitric acid (1.3).....	9 areas.

The density was distinctly less in the case of the acid-bathed plates than in the others.

J. M. Eder (8), in his discussion of the "Nature of the Latent Image," comes to the view that the latent image consists partly of sub-bromide of different stability toward thiosulphate and towards nitric acid. As mentioned earlier in this paper, that part (stable towards nitric acid) of the developable image which remains after primary fixation, has been frequently ascribed to an organic silver compound. But under the conditions of our experiments no organic compound could be formed (9), and hence the conclusion of Dr. Eder may be accepted without question. There is no longer the opportunity, in the case of gelatine or collodion emulsions, to give another interpretation to the fact of the permanency of part of the latent image.

KARL SCHAUM.

EDUARD SCHLOEMANN.

AN American photographer, I. Benjamin, of Cincinnati, is establishing himself in business in Paris. His enterprise was marked by a meeting at his studio with a few of his professional brethren, including S. L. Stern, of Milwaukee; J. C. Strauss, St. Louis; G. W. Edmonton, Cleveland, and others, which occasion of fraternization is the subject of a photograph in the current issue of the "Photo Era." Mr. Benjamin, so we learn from the same journal, invades Europe with high credentials from America. He studied art at the Cincinnati Art Academy from 1883 to 1888, and was the founder of the Art Students' League of Cincinnati, serving as its president for seven years. He twice received the Grand Prize of the Photographer's Association of Ohio, and was awarded a silver medal for portraiture at the International Exhibition of the American Institute of New York in 1896. He was medalled by the Michigan Photographers' Association, and

also by the P. A. of A. He received a gold medal for miniatures at the Milwaukee Convention; also Salon honors at Philadelphia, Pittsburgh, and Ohio, and a silver medal from the International Exhibition at Turin, Italy. He has been active professionally in Cincinnati for nineteen years.

Mr. G. H. Stanford, Boscombe, has had accepted, by the King of Spain, three photographs of His Majesty taken during the latter's visit to Cowes.

(\*) "Sitzungsberichte K. Akad. Wien," 114, IIA. July, 1905; "Zeitschrift für Wiss. Phot." III. 329 to 353, 1905.

(\*) Karl Schaum ("Phys. Zeitschrift," II. 552, 1901), has brought forward the possibility that the vehicle of the emulsion in those places where there is exposed silver bromide, through the action of the halogens, may be altered by the decomposition products of the developer, so that a separation of silver from the developer may be promoted. This supposition appears very probable in the case of the silicic emulsion.

## THE LAWS OF THE STEREOSCOPE AND STEREOSCOPIC TRUTH.

### III.\*

To produce a true stereo picture is a much more delicate matter than one would think, and when we say true we will consider the practical side of the question, knowing well that the theoretical truth cannot be attained, for a reason which, amongst others, has already been made clear. To approach as near as possible to stereoscopic truth, the following conditions should be fulfilled:—

1. Choose the point of view—that is to say, place yourself in such a way as to see the subject as one wishes to see it in the stereoscope.

2. Place the apparatus at the said point of view, so that the lenses occupy the place of the eyes.

3. Take care, in consequence, that the lenses are separated by the same distance as the eyes, the normal separation of which is 6.5 cm.

4. Mount the prints in such a way that the right eye sees that produced by the lens on the right, and the left eye the other. The expression ordinarily used by the majority of authors is: "To mount at the right the print of the left," a piece of instruction which cannot be more erroneous. The fact is that photography produces an upside down reversal of the images. To see the double print uncut, it is reversed; but by doing this one has brought the right print to the left. After cutting them the prints should be mounted in their respective places.

5. Theoretically, the prints should be cut so that one does not contain anything which is not contained in the other; but this is impossible, for the images are different, and cannot be superimposed. Practically it is sufficient if the front planes have their homologues in the two images, for it is those which ought to have the greatest relief. In this case the rest will be satisfactory, although there will be still a small excess of the distant plane on the right of the image on the left, and a similar excess of the distant plane of the left of the right image.

6. It is useful to mount the prints on a black ground. The image can then appear as though seen through an open window, if one sacrifices a half millimetre vertically on the right of the right print, and also a half millimetre on the left of the left print. This operation will bring the black ground to the front plane, for the homologous vertical lines will be one millimetre nearer than the front planes of the image itself. The eyes ought then to converge more to see the black ground than to see the subject, which will locate the bottom in front of the picture, and will act like a window. This is a point of which the International Congress of Photography did not think when it fixed at 70 millimetres the separation of homologous sides of the stereoscopic openings, after having fixed on the same separation of 70 millimetres for homologous points in the stereoscopic couple. And as regards this last, the Congress ought to have made clear whether it intended to speak of points situated on the horizon or in the foreground.

7. In the stereoscope the images ought to be seen with the same convergence of the visual rays as that which existed vis-à-vis in nature. The most certain means of arriving at this result is to mount the two prints so as to separate by 6.5 cm. homologous points situated on the horizon, and to use a stereoscope of which the oculars are full lenses—and not prisms—separated also by 6.5 cm. from centre to centre. Then one will look at the horizon with parallel vision, and the convergence towards the foreground planes proceeds naturally. It is unfortunate that commercial stereoscopes do not satisfy this condition; their lenses are separated too much; in consequence of which one does not look through their centres but through the eyes. The result is that they act like prisms, which produces an apparent distortion and displacement of the images in bringing them nearer. This is why in this case they ought to have a separation greater than that which alone is rational, and as we shall indi-

cate. The separation which is usual in these instruments is for similar points on the horizon.

8. Finally, the distance between the eyes and the print should be equal to the focal length of the objectives. This is indispensable for it is only under this condition that the images will occupy the desired angle. If lenses are used, it is necessary to arrange the apparatus, so that the angle occupied by the image is good, that on the retina the dimension of the image corresponds to that which will produce nature itself.

### Tangible Proofs.

A referendum has been made apropos of stereoscopic pictures obtained under abnormal conditions, and giving presumably the representation of the object photographed, and some incredible conclusions have been printed. Among others may be cited the one of M. Donnadieu, who, in his last work, pretends to have obtained the better representation of a cube by photographing it with a separation of only one centimetre. Those who expressed an opinion on this in the referendum have never seen the model in nature.

It is not the way to proceed. If the opinion of people is wanted on the resemblance of a portrait, it is necessary to place side by side the original sitter or a true stereogram, which may be used instead. It is in this way which we shall do, in the two examples which will serve to resume to the reader of all that we have said and shall say.

We have here, first, a well known work of art in bronze—Les Liliules. It was photographed three times at the same distance, with different separation of the lenses; the lens on the right kept in its place. The second of these images corresponds to normal separation of 6.5 cm. To see the three stereograms ought then to vary the convergence of the visual rays. It is this reason that the three couples are not at the same distance separation.

I have mounted the whole at a separation greater than that which I strongly recommend, so that they can be seen with the commercial stereoscopes. Whatever be the kind of stereoscope employed it not be reproduced by the exact convergence as it ought to be. One may suppose that the middle statuette represents the dimension apparently agreeing with reality.

Examine this statuette well, and you will immediately have the impression that of two others, that to the left is further off from you and it looks larger. That on the right, on the contrary, appears to come nearer and to be smaller, and at the same time the two images on the right are identical, printed from the same negative, and those on the left have exactly the same dimensions, for they were photographed at the same distance.

If you compare, then, the attitude of the three statues you ought to be able to recognise that that on the left is the "most flat" of the three; there is a slight difference between the planes occupied by the two hands and by the two feet. An artist will recognise at once that the right arm, from the shoulder to the elbow, and the right leg, from the knee to the foot, are too short. The robe flattens the calf, and the pedestal seems oval and larger than in Figure, which agrees with reality. If now we turn to the third figure, that on the right, we find the relief exaggerated. The pedestal is out of depth, the figure takes an immense stride, the right leg and right arm are too long, and the robe is distended as though blown by the wind.

If one demanded in a referendum to an unprejudiced public, which of the three stereograms was the best, it is probable that 90 per cent. of the observers would say that with the exaggerated relief. Why? Because their stereoscopic education is falsified by the exaggerated relief which is found in almost all existing stereograms, which are almost all made with too great a separation of the lenses.

What is the result of this state of things? Let us take the view

\* The following is the conclusion of the translation of the paper by M. Goderus, the preceding portions of which appeared in the BRITISH JOURNAL for Aug. 17 and 24. The figures referred to in the present instalment accompanied the text published in last week's issue.

\* The referendum here referred to took place at the beginning of this year under the auspices of the Association Belge, de Photographie.—Eds. B.J.P.

of towns; when you actually see them after the views seen in the stereoscope, you do not recognise them, or if you do you have some such reflections as the following: "I certainly imagined that this place was much grander: that the Rue N— certainly was not as large as this!"

Here is another example in which two stereograms were made of the same subject, a globe, with the same angle of convergence, but at different distances. The left image was made at the distance of a metre, with a separation of 6.5 cm. between the axes of the two lenses. The right image was obtained with a separation of 13 cm. and two metres distance.

The angle of convergence remained the same as in nature. This angle is also the same on the proofs, where the centres of the two spheres are respectively equidistant—namely, cm., contrary to our theory, for the reasons indicated apropos of the previous example. When these two globes are examined in the stereoscope, they will appear as though their centres were at the same distances from the eyes—that is to say, they appear to be side by side at one metre from the observer. However, the little globe does not appear as though it were a reduction of the large one. This alone corresponds to the proportions of the model, and gives the true inclination of the globe on its axis.

When they are carefully examined it will be seen that the little globe seems less inclined than the large one; their axes are not parallel, as they should be if the small one was an exact reduction of the large one. This is due to the fact that the perspective lines of the little globe, seen at the distance of one metre, like the large one, correspond to those of an object seen at double the distance and with a double separation of the eyes.

To those who may ask why we have not mounted the prints so as to show the pedestals of the two globes of the same height, we reply that the lenses were exactly opposite the centre of the map of the world. This centre in the case of both images should be on the horizon line.

One could have reversed this example and photographed first at

two metres with the normal separation of 6.5 cm., and then at one metre with half the separation. This would then result in the little globe being exactly represented as in nature, and the large one would be deformed in its proportions.

### The Probable Objections.

1. If the statues were mounted so that they were equidistant two by two, they would be aligned on the same plane. That is true, but the perspective of depth of the first and third would still be more false than actually, for the components do not answer better to the angle of convergence which determines these lines.

2. If the prints of the two little globes were mounted with a separation greater than that of the large ones, the fusion of the first planes would be situated further behind. It is still true that one could create the illusion of the true distance of the object and its true dimensions as regards height, but its proportions would remain changed. One would not be able to perceive this vis-à-vis with an isolated object, of which the lines of perspective are not very accentuated, but in a landscape, the view of a town, an interior, a geometrical solid, a portrait, especially, the fact will immediately become evident.

Here, without comments, is a striking example: two portraits of the same person, the one taken at a distance and then enlarged, and the other taken close to, and then subsequently reduced, so that they are the same size. As the one can be seen at a convenient distance, while it is not possible to get close enough to the other to see it, this latter, which is, however, equally true, though it was made with a short focus lens, seems a monstrosity.

In certain cases it is this want of *a priori* evidence, this evidence to convince the eyes, which induces thoughtless people to lay down the laws which we have considered, because they have not observed before making both the negative and the print, they have arrived at a result which seems satisfactory to them, in default of an immediate comparison. From that to formulate the erroneous principles is only a step; as for the experts, they are always discovering the most ridiculous theories.

A. GODERUS.

## REPRODUCTIONS BY LITHO-PHOTOGRAVURE.

The above title is not that at the head of an article in Tuesday's "Times," reviewing the invention of Sir Joseph Wilson-Swan and his son, Mr. Donald Cameron-Swan, which is the subject of a communication from a correspondent. Yet as the article raises several points in book production, which may be noted even by those whose enterprises in this direction do not extend beyond a professional or trade catalogue, it may be advisable for us to quote a large portion of the writer's text.

The new method combines the intaglio (or photogravure) process of making engraved plates, with the lithographic process of printing. In other words, it combines the most perfect process of photo-engraving with one of the cheapest and most rapid printing methods. The advantages gained will be more clearly seen if we review some of the illustrating processes of the past half century, considering their relative strengths and weaknesses, which course will show clearly the many problems solved by a discovery that effect the union of two well-known methods.

In wood-engraving, the dominant style of illustration through most of the 19th century, which preserved for us the works of Leech, Tenniel, Harrison, Weir, Whympere, and many another, the print is made from the surface of a wood block (or an electrotype therefrom), from which the whites of the pictures have been cut away by gravers, guided by hand and brain. In half-tone engraving, developed in the last quarter of a century, the print is made from an enormous number of tiny dots left on the surface of a metal plate by the etching away of the intermediate spaces by acid, guided by photography. In wood-engraving the lights and shades are governed by the size, shape, and distribution of patches of black and of white, and the variety of size, shape, and distance apart is practically unlimited. In half-tone the dots are distributed evenly all over the surface of the engraving, and the difference between lights and shades is made by the sizes of the dots.

### The Bane of Art Paper.

In wood-engraving the whites—which are not to receive or print ink—may be cut very deep in comparison to their width; in half-tone the spaces between the dots are exceedingly shallow, and this difference has caused a complete revolution in the making of paper and building of printing presses, because neither the paper nor the machines used for the wood-engravings are suitable for the half-tone. Soft paper, such as all bookmen love, cannot be printed with the shallow half-tone; and the relatively heavy masses of ink that are needed to give good blacks on such absorbent paper, cannot be used on the half-tone without filling its shallow hollows and giving one even smudge. To meet the requirements of the shallow block, modern papers, known as "art," "imitation art," and "super-calendered," have been introduced, all with a considerable amount of "loading"—usually of kaolin or China clay—in, or on their surfaces. These papers are truly "lath and plaster," for their interior is woody fibre, disintegrated as finely as possible to prevent the slightest lumpiness, and their faces are simply so much cement. They are very liable to scratch, when feeding into, or passing through, the printing machines, and when folding for binding; they are so brittle that they cannot be folded tightly, to make a hard back which is needed for durable binding; when bound, the leaves are liable to break and fall apart; and they are so sensitive to moisture that it is almost impossible to gild or colour the edges of books, and that if leaves become wet, or even thoroughly damp, they will stick together and their surfaces can never be separated. Moreover, these modern papers are very heavy for a given thickness, so that books of any considerable size are uncomfortable, and even painful, to handle.

### Photogravure and Litho.

Printing from very shallow blocks necessitates the use of very stiff

inks, with a maximum of finely ground pigment in a minimum of vehicle. This, in turn, necessitates printing machinery having very great rolling and distributing power.

Even with its specialised paper and machinery, half-tone fails to give us the clean, brilliant whites and blacks of the wood-engraving; and for a photo-mechanical process that can rival the older methods and give us really fine individual prints, we must look to photogravure. In this process the printing plate is etched in intaglio—and the ink is transferred to the print from the hollows of the plate, while the prominent parts represent the whites. In this case light and shade largely depend upon the varying depths of the hollows, and, consequently, the varying thicknesses of the ink. Photogravure prints may be made upon the old and durable papers, and the results are most satisfactory, but it is necessary to ink by hand, and to remove by hand the ink from the raised surface of the plate that represents the whites. Obviously this means slow and expensive printing. Many efforts have been made to print photogravure by machinery, but the difficulty has always been with the "wiper," to remove the ink from the whites. In practice it is found that any wiper which successfully removes the ink very quickly wears the plate, even if steel faced.

In addition to the surface printing and intaglio printing methods, we have the lithographic principle, in which the "whites" of the printing surface are water-absorbing, and repel greasy ink, while the shadows are dry parts, which freely take the ink from the rollers and transfer it to the paper. In this case much of the difficulty arising from the shallowness of the half-tone block is avoided, for even the smallest of spaces can be kept free from ink; and half-tones can be transferred to and printed from lithographic stones or plates.

Moreover, durable papers without ultra-glazed surfaces may be used in the lithographic machine; but there is still the difficulty of the fine dots, the impossibility of giving a heavy inking, and the absence of strong, vigorous black and whites.

#### Photogravure with a Screen.

By Sir Joseph Wilson-Swan's invention, an intaglio or photogravure plate is made in the ordinary way, but with the introduction of a half-tone screen grain. Unlike other photogravure plates, however, the surface is made water-absorbent, and, therefore, ink-repellent, while the hollows (which may be as broad and deep as necessary) take and transfer the ink. Thus all "wiping" and consequent wear of the surface is avoided, and the plates can be, and have been, printed in ordinary lithographic machines running at the speed of several hundred sheets an hour. It is possible to print text (transferred to litho plates) at the same time as the illustration. For some time the method will be more expensive than half-tone printing, but before very long it ought to be possible to produce the average illustrated book or magazine at about the present cost, saving on the cost of paper what is lost by the somewhat slower speed and therefore higher cost of printing. And the book or magazine will be more enduring, pleasanter to the touch, more comforting to the eyes, and will have more vigour, variety, and beauty in its illustrations.

The development of such a method may enable lithography to retake its old high position, as fully the equal, if not the superior, of letterpress printing, a position which it lost largely through the development of half-tone illustration. In any case it will mean enormous modifications in the printing, the papermaking, and the bookbinding industries, and will prove a great gratification to all lovers of books and of illustration.

## POSING STOUT PEOPLE.

The illustrations here shown deserve consideration, writes a correspondent of the "Photo-Beacon," as they tell very clearly the right and the wrong way, from the sitter's standpoint, of posing a stout person. The left-hand print shows the effect when the subject is

recommends that on the posing-chair there be placed an upper storey, which consists of a cushioned seat, about a foot high at the back, and nothing in front. The upper surface is not straight, but part of a circle with the convex side of the curve uppermost. This seat is

permitted to sit in a chair, the right-hand print when she is asked to stand behind the same chair and lean a little forward over it, while at the same time the camera is kept fairly low. The bust has more of a downward tendency, while the upward look of the camera renders less conspicuous the double chin. Another photographer

very effective. The photographer who sends in the two prints reproduced says he finds leaning over the back of the chair a very successful method of handling children who are dressed in the loose blouses that are now so popular, as it prevents the clothing from bunching up.

## THREE-COLOUR AND FOUR-COLOUR PHOTOGRAPHY.

THE following article continues the series of papers by Baron von Hübl, translations of which we have given in recent issues.\* The first portion expresses the author's views of the three-colour filters and the methods of adjusting them, and the remaining part of the article deals with the theory and the limitations of the four-colour system of photographic reproduction. The former is from "Das Atelier," the latter from the "Wiener Mittheilungen."

The filters used for three-colour work must, as already mentioned, have a definite spectroscopic quality, which must correspond to the fundamental colours laid down in the preceding article, but the colour sensitiveness of the plate must also be taken into consideration. Each sort of plate requires therefore another filter, and a simple method of finding out and controlling the filters is of considerable practical value.

All experiments to determine the filters by means of a spectro-scope lead to no results, as in this method the peculiarities of the plate can hardly be taken into consideration, and when one speaks of "spectroscopically tested filters" it is a phrase which does not mean much.

Something more may be attained by means of a spectrograph, for by this method the spectroscopic sensitiveness of the plate receives full recognition, and from the photographed spectrum conclusions can be drawn as to the correct quality of the filter.

But even this method is not to be much recommended, for quite independent of the fact that it involves a good deal of labour, it is also uncertain. In the first place, we do not know exactly what the spectrogram of a correct filter should be, for the connection between spectrum and pigmentary colours is extremely complicated (in the spectrograph and the camera quite different light ratios exist), and

finally the extension and form of photographed spectrum band depends to a considerable extent upon the time of exposure.

The simplest and safest method of determining and controlling the filters is by photographing pigmentary colours by the aid of a three-colour sensitometer or a colour chart. The colours for this chart should be vermilion red, ultramarine, and yellowish green, and they should be so chosen that when mixed by means of 120 deg. sectors on a colour top they should give a neutral grey, and should thus possess equal colouring powers. The yellow mixed with an equal quantity of ultramarine should give a neutral green. (The position of the four colours used by von Hübl is shown in Fig. 8, with the fundamental triangle of yellow, crimson, and blue-green.) In the negative for the crimson constituent image, plate and filter must be so adjusted that crimson pigments are as inactive as black, those between blue-green and yellow be as active as white, and the vermilion lying midway between crimson and yellow and the ultramarine lying midway between crimson and blue-green must be half-tone in the negative. There can be no doubt that these mean colours, vermilion and ultramarine, can be formed by the combination of the constituent pictures, whether this is effected by additive or subtractive mixture, for they can only be formed by  $\frac{1}{2}$  crimson +  $\frac{1}{2}$  yellow or  $\frac{1}{2}$  crimson +  $\frac{1}{2}$  blue-green.

### FOUR-COLOUR PHOTOGRAPHY.

All three-coloured prints show the defect of impure compound colours, which give the print a dirty unpleasant appearance. This phenomenon—as is generally known—is specially noticeable in the mixture of the blue and yellow, giving a defective green, which is characteristic of trichromatic prints. The defect cannot be obviated by retouching the red printing plate, but it may be reduced to a tolerable extent; for three-colour pigment or gum printing the negatives must be retouched, which is only possible to a limited extent.

The possibility of this four-colour photography was pointed out by Dr. Eder in 1836,<sup>1</sup> in the following words: "According to Hering there are four fundamental colours, red, yellow, green, and blue. Working according to this theory, all the manipulations necessary for three-colour printing may be adapted without difficulty to a four-colour system, and a four-colour print would be the result, in the production of which there is nothing actually to overcome, and the system ought to give very satisfactory results."

The theoretical basis of the process was explained by me in the first edition of "Die Dreifarben Photographie," 1897, p. 77, as follows: "For a four-colour print, against which there are no theoretical objections, the fundamental colours must be so chosen that they are at equal distances on the periphery of a colour circle. As all compound colours can then be enclosed in a square, which covers almost the whole of the colour circle, it is not necessary to lay such stress on the purity of the colours. Thus, for instance, the stable colours, chrome yellow, alizarine lake, then a blue and a green lake, will be quite suitable to reproduce practically all colours."

The above four colours correspond to Hering's fundamental colours, which are also the foundation for the colour circle. Fig. 1 shows the colour circle, and the inscribed square, in the corners of which lie the four colours, includes all shades and tones of colours formed by admixture of the same. As pure yellow cannot be formed out of two other pigmentary colours, this system is the only fundamental one that is practically useful.

Hering's fundamental colours only excite one colour-sensation. The blue is neither green nor reddish, and corresponds to ultramarine; red excites neither yellow nor blue, and corresponds to carmine; the yellow, neither greenish nor red, is represented by a medium chrome yellow, and the fourth colour is a pure green, which does not excite either blue or yellow. Each pair of these colours is complementary, and if the colours are compared to spectrum lights, as may be taken from Fig. 1, they will have about the following wave lengths: Blue  $\lambda$  468, yellow  $\lambda$  573, green  $\lambda$  510. The red is wanting in the spectrum, as it is bluer than the spectrum red, and can be defined as that red which is complementary to the green at  $\lambda$  510.

Thus the colours of four constituent images are determined, and

<sup>1</sup> Schriften des Vereines zur Verbreitung naturwissenschaftlicher Kenntnisse 1836, p. 255.

Attempts have been made to obviate this defect by adding to the red, yellow, and blue impressions a green one, thus striving to split up the original into four constituent prints, and using four printings. This process, which is suitably called four-colour photography, differs from existing four-colour printing, in that four bright colours are used, whilst in the latter a black-key plate is added to three colours.

\* B.J.P., June 2 and August 10, 1906.

the photographic splitting up of the original must correspond to them. The necessary colour sensitiveness of the plates and the behaviour of the filters can be easily determined by "splitting up the absorption spectra,"<sup>2</sup> and this process was specially mentioned for

Fig. 1.

Chart corresponding with the Hering primary colours . . . colour scheme according to C. G. Zander.

four-colour printing in the first edition of "Die Dreifarben Photographie," p. 86. Fig. 2 is the result thus obtained."

The four curves show the necessary sensitising of the plates, and if panchromatic plates are used the filters must be so arranged that they only transmit light corresponding to the curves of sensitiveness.

From this diagram it is easily seen that the four filters must be

Fig. 2.

carmine red, blue, green, and yellow, a result which is also easily reached by simple consideration. Assuming that panchromatic plates are used, the colour of the filter must always be complementary to the printing colour, and, as every pair of printing colours is complementary, the filters and printing inks are of the same colours. The negative for the carmine printing is made through a green filter, that for the green printing through a carmine filter, and so on.

The preparation of plates with the necessary colour sensitiveness and of the filters presents no difficulties. When, however, a four-colour photograph is attempted by this method, it will soon be seen that the expected result cannot be attained, for dirty colours will always be obtained.

If, for instance, in the composite print pure colours are to be formed the fundamental colours as, for instance, green and crim-

son) present in the original must be obviously printed with the corresponding inks; further, yellow-green, and blue-green must be formed by mixtures of green + blue or green + yellow, violet only from blue + carmine.

That these requirements are not to be fulfilled, however, the following considerations show: If we imagine the four fundamental colours spread saturated on paper, in the negative, to comply with these requirements for the green print, the green field must be clear glass; the yellow, red, and blue, however, will be dense. Generally speaking therefore in each of the three negatives three colours must always act like white, the fourth, however, like black. But we consider the rays reflected from the four fundamental colours. Fig. 3, the impossibility of obtaining this will be easily seen.

Fig. 3.

We can photograph yellow brighter than green if the plate sensitised for the zone M; it is, however, impossible to photograph green like white, and yellow like black, for the portion P of the absorption spectrum is common to the two colours, and thus, with a plate sensitive for O, carmine can be photographed like white, as blue like black, but not the reverse, for the difference in the zone is too little. If we examine the sensitiveness of the plates in Fig. 2, it will be easily seen that the green field in the reproduction will be reproduced, not alone by green, but by green + blue + yellow. As here blue and green are complementary, and thus combine to form black, a blackish and not a pure green is formed. We therefore obtain at least no better result than with three-colour printing, which the green is degraded by the red printing.

Exactly the same thing occurs in the reproduction of all other colours. They will always be degraded by a complementary pair of colours, and will therefore appear more impure than in three-colour printing. The theory is in both cases equally correct, on it assumes ideal printing inks, and only because these do not correspond to the required conditions, especially as regards their purity perfect results are not obtainable with either process.

For these reasons four-colour printing cannot be preferred to the present three-colour method. If, besides this, one takes into consideration the much greater trouble of four-colour photography, and that the chances of errors are increased, and considering also the want of accurate register is extremely irritating, and that in the mixture of green pigments certain irregularities appear,<sup>3</sup> etc., the view that this process not only does not offer the expected advantages, but must give worse results than three-colour printing, is correct.

For these reasons the four-colour process was not mentioned in the second edition of my book.

Quite recently C. G. Zander has endeavoured to again introduce four-colour printing into practice. Zander proceeds from exact analogous considerations, and also uses a colour circle for the choice of the colours, in which, however, the colours do not include equal regions, but correspond to their extension in the normal solar spectrum. He thus obtains the following fundamental colours: Orange  $\lambda$  589, blue  $\lambda$  458, and green 522, and a crimson complementary to this green.

Against this system of colours must be advanced that it contains no yellow, but an orange of about the same colour as a chromatic orange. No pure yellow therefore can be formed with this colour

<sup>2</sup> Die Dreifarben photographie, 2nd Edit., p. 92.

<sup>3</sup> Archiv für Wissenschaftliche Photographie, 1899, p. 304.

Further, these four colours do not correspond to the requirement that, mixed in equal proportions, they should give a grey, for this is only possible when each pair is complementary. Green and crimson are thus chosen, but not orange and blue, for the former of  $\lambda 58$  is not complementary to the reddish blue at  $\lambda 458$ , but to the greenish blue at  $\lambda 484$ , near the F line.

These properties are seen at once if the colours are inserted in the approximately correct colour circle in Fig. 1. They then form the four-sided figure shown by the dotted line, and this is not symmetrical.

It is scarcely to be assumed that these colours will answer better in practice than Hering's fundamental colours, all the more so as the difficulties of splitting them up by photography increases the nearer the colours approach one another; the colours, orange, crimson, and blue-violet, lying so close to one another, behave in this respect worse than Hering's fundamental colours.

In practice, moreover, this choice of colours does not seem to correspond, for in another place<sup>4</sup>, magenta-red, citron-yellow, emerald green, and ultramarine are introduced, which are very near Hering's fundamental colours.

In spite of the above described failings of the four-colour process, it does not preclude the fact that it can sometimes give better results than three-colour printing, only there must be considerable fine-etching of the printing plates. This must be done on all four plates, and is considerably more than is necessary with three-colour work.

Without this manual help the process cannot be employed, and for this reason also four-colour photography is valueless for carbon and gum printing.

ARTHUR VON HUBL.

## Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

The following applications for patents were made between August 13 to 18:—

ETCHING PROCESS.—No. 18,217. A photographic etching process. Anton Dillmann, 61, Chancery Lane, London, E.C.

CAMERAS.—No. 18,260. Improvements relating to mounting swinging lenses on photographic cameras. Arthur Lewis Adams, Birkbeck Bank Chambers, Southampton Buildings, London, E.C.

PORTABLE APPARATUS.—No. 18,345. Improvements in apparatus for travelling photographers. Jean Schmidt, 31, Bedford Street, Strand, London, W.C.

CAMERAS.—No. 18,393. Improvements in photographic cameras. Cecil Alexander Elliott, 37, Essex Street, Strand, London, W.C.

DOUBLE OBJECTIVES.—No. 18,525. Improvements in double objectives. Moritz von Rohr, Jena, Germany.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PHOTOGRAPHIC PAPERS.—No. 2,057, 1906. The invention has reference to the patent of Hoffsummer, No. 17,303, 1905 (B.J., November 3, 1905), consisting in the use of a porous fibrous coating on paper to bear an emulsion. It is now suggested that the protective layer should be of pure photographic paper, such that the emulsion may penetrate to a partial extent. This upper layer of paper may be assisted in its action by further protective layers of any suitable kind, which are applied in the ordinary manner on the upper surface of the paper before or after its combination with the under paper, or which are embedded between the two layers of paper. For obtaining matt pictures which extend into the substance of the paper, the photographically pure protective paper may be employed only slightly sized or even unsized. The coating of the protective paper itself alone, must then take place

before its combination with the under foundation paper, otherwise the adhesive substance, such, for instance, as starch, which combines the two papers, may penetrate so far into the protective paper that the intended effect of producing a matt sunken-in picture would not be attained, as the pores (which are purposely left partially or entirely open) of the slightly sized or unsized protective paper, would then be filled with the adhesive substance. This can, however, not take place if the pores of the protective paper be already filled with the constituents of the coating before the protective paper is combined with the under raw paper. It is thus possible to obtain a matt picture. Ignaz Hoffsummer, 11, Schenkel Strasse, Düren, Germany.

PRINTING MACHINES.—No. 17,895, 1905. The invention consists of a hand-fed machine for printing bromide and other paper by artificial light. The object of the machine is to effect the rapid changing of one sheet of bromide paper, after exposure with a minimum expenditure of time, to effect the accurate register of each sheet in the same position for exposure on the negative, and to effect the close contact of the surface of the bromide paper with the negative which is being reproduced. Means are provided for lifting the pressure board away from the negative for the introduction of the bromide paper into position, for replacing the pressure board against the negative and immediately

thereupon lowering a shutter by means of which bromide paper may be exposed to actinic light. These operations are effected by the employment of a treadle or hand levers, whose movement in one direction effects the withdrawal of the pressure board *A* from the negative and whose movement in the opposition direction effects or permits its return, and whose further movement lowers the shutter *e* for the exposure. The treadle or hand lever is connected by a rod to a bracket *o*, upon which the pressure board is carried and an adjustable collar on this rod engages a lever *m*, which operates the shutter. This lever is held normally in the position in which the shutter is closed under the

<sup>4</sup> Zeitschrift für Reproduktionstechnik, 1906, p. 30.

action of a spiral or other spring *j*, the other end of the spring being attached to a vertical arm *k*, pivoted on the base of the machine, and connected by a link *l*, to the pressure board, or the bracket on which the pressure board is carried, and conveying the action of the spring to the pressure board, and thus normally maintaining it with pressure against the negative. Means are also provided for firmly securing the negative in the machine, and for so disposing the negative, that any part of it may be printed from. By depressing one end of the treadle *s*, say, with the toe, the pressure board *h* is pulled away from the negative, by the pressure transmitted to it through the rod *o* and the bracket *n*, thus permitting the changing of the bromide paper. On releasing the pressure of the toe on the treadle the pressure board *h* is brought back into position against the negative by the influence of the spring *j* thus pressing the bromide paper against the negative; while on depressing the other end of the treadle, say, with the heel, the pressure on the pressure board *h* is increased and the shutter *e* is opened, thus exposing the bromide paper to the actinic light transmitted through the negative. This operation, it will be understood, takes place while the rod *o* is being compressed. On releasing the pressure of the heel in the treadle *s* the pressure on the pressure board *h* lessens, and the shutter *e* closes under the action of the spring *j*, which normally maintains the shutter operating lever *m* in the position in which the shutter *e* is closed. George Hana, 22, Bedford Street, Strand, London, W.C.

**EXPOSING DEVICES.**—No. 5,926, 1906. The apparatus, which requires the figures for its explanation, consists of an adapter and light tight envelopes. The adapter is a frame with no sliding door, and of any size to suit the plate, or film, recessed and velveted at the right-hand end, and with a daylight opening in it. It has a hinged door at the back, flanged at the right-hand end, and recessed at both ends for the projection of the two tabs of the light tight envelopes, which, when drawn out at the right-hand end, uncovers the sensitive plate or film for exposure, and when drawn out at the left-hand end return the light-tight cover of the dark envelope, and thereby secure against light, the plate or film just exposed. Two long springs of steel or other material are fitted, one at each end of the hinged door, or they may be fitted to any part of the door, to keep the plate or film in register, and, preferably, a shaped triple slotted catch is fitted engaging with screw nails to secure the hinged door when closed. Robert Ballantine, Arthur Ballantine, H. W. Ballantine, 101 and 107, Buchanan Street, Glasgow, and John Linstrum, 206, Abercomby Street, Calton, Glasgow.

## Commercial & Legal Intelligence.

**UNPREMEDITATED ART.**—On an understanding that James Crawley (otherwise John Clifford) and Albert Vale would take a dozen photographs of points of interest in Worthing for him, being supplied with apparatus and materials, and paid for their time, Mr. Percy F. White, chemist, of Park Road, provided them with a camera and stand, a dozen "half-plates," and a focussing cloth. Mr. White had had previous transactions with Crawley, and found him straightforward. This time the things were not returned. The two men were arrested at Bognor. They told P.C. Slade they sold the camera at Chichester for 12s.; they also told him where to find the plates. "It's a disgrace, but I will bear it alone," said Vale. "I don't wish to screen myself, but it was not premeditated," explained Crawley. A Chichester photographer, Frederick Henry Robinson, of 5, St. Pancras, told the Bench that he bought the camera, stand, and cloth from Crawley on the 15th inst., for 12s., to "help him to get to London." The following day P.C. White saw the two men trying to sell a hand camera at Bognor, and took them to Sergeant Thomas, who detained them, and telephoned to the Worthing police. On being formally charged, both prisoners pleaded guilty, and the Bench passed sentence of one month's hard labour.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society	Subject.
1.....	Worthing Camera Club.....	Outing to Storrington, to Thake Woods or West Chillington.
1.....	Leeds Camera Club.....	Outing to Clapham.
3.....	South London Photo. Society..	Conversazione and Opening of Winter Session.
3.....	Bowes Pk. and Dia. Ph. Soc. ...	"The Kallotype Process." Demonstrated. Messrs. W. T. P. Cunneham and A. J. Craeton.
4.....	Hackney Photographic Society	Members' Lantern Slides.
5.....	North Middlesex Photo. Soc. ...	Lantern Slide and Print Competition.
6.....	Hull Photographic Society .....	General Meeting.

**WALSALL PHOTOGRAPHIC SOCIETY.**—This society had its annual outing on Thursday, when some thirty members and friends visited Tewkesbury. Leaving Walsall about 6.30 a.m. the party arrived at its destination about nine o'clock. The weather was fine. As well known, Tewkesbury affords many attractions to photographers and during the morning the members improved the shining hour by capturing some of the best bits of the ancient town, some of the quaint old buildings, and the famous abbey being laid under contribution. Many of the buildings have been "modernised," but there is still plenty of scope for the photographer to come across subjects which are pleasing from a picturesque point of view at the same time possess historic interest. As a result of the morning's efforts, many capital pictures were secured, and these will no doubt be seen at some of the future meetings of the society during the coming session, as the society offers prizes for the best series of lantern slides in connection with these outings. In the afternoon the party proceeded to Nafford by steamer, where, on arrival, some of the party went on to Eckington village, a picturesque spot affording pretty little subjects. In due course the excursionists entrained and arrived back at Walsall, after having taken part in one of the most enjoyable outings ever held in connection with the society.

**SOUTHAMPTON CAMERA CLUB.**—Mr. C. D. Kay lectured, on Monday evening, on "Enlarged Negatives." Preceding a demonstration of the making of an enlarged negative upon a 12 x 10 plate, the lecturer gave a lucid explanation of the process, dealing first with the apparatus required for both daylight and artificial light work. Having dealt with the relative necessities of the original negative and the positive, it was pointed out that two methods were open for procedure, either for an enlarged positive and a contact negative therefrom, or an enlarged negative from a contact positive, but the latter was the method advised. It was urged that while enlargements had not in themselves any merit of the score of size simply, yet opportunity was given on the enlarged negative of dealing with any undesirable features from a pictorial point of view, and it was pointed out that while in paper negative this was perhaps more readily done, yet the disadvantage of grain in the paper had to be reckoned with. The lecturer advocated the use of artificial light, chiefly from the point of advantage of its more regular character.

**PRESS PHOTOGRAPHY.**—We are in receipt of the prospectus of the Practical Correspondence College, Thanet House, Strand, London, W.C., containing particulars of the postal courses of tuition in several special branches of modern illustrative methods. Mr. W. Muir directs a course in Press photography, by which to put the amateur, or the professional photographer, for that matter, in the way of cultivating the ninety-six journals in London which pay for illustrated matter. Mr. Muir has been through the mill of Press photography himself, and we can hardly imagine any one failing to benefit from the fruits, delivered by post, of his diverse experiences. The second course, "Commercial and Advertising Photography," is in the hands of Mr. Percie T. Edwards, who also places the experience of a long career as a designer and photographer at the disposal of his students. The booklet, "Cash and the Camera," in which particulars of the courses are given, is certainly as good an example as could be wanted of the qualifications of the school to advise those commencing such a branch of commercial photography.

## New Apparatus, &c.

**Photo-Title Outfit.** Sold by W. Butcher and Sons, Camera House, St. Bride Street, London, E.C.

This useful outfit for printing titles on negatives is an improvement on the sets of the same description issued by Messrs. Butcher last year, inasmuch as there is a larger assortment of letters, and the whole outfit of type-holder, ink-pad, pliers, and gauge is contained in the type case. The three shilling set includes 70 capitals, 12 small letters, 23 figures, and 40 stops, whilst for 4s. an outfit

may be obtained containing a still larger equipment of type. As with the previous sets, the inked type is pressed gently on to the negative and the impression lightly dusted over with the opaque powder supplied, a dense lettering resulting, which gives a clear white title when prints are taken from the negative. The outfit should be found very convenient to those who prepare postcards for publication, and on many occasions when it is desirable to attach the title to a negative.

## News and Notes.

A PHOTOGRAPHER named Dilke was charged at the Bedford Police Court last week with attempted suicide. The defendant came home on August 17 and drank a quantity of ammonia from a bottle which he used in his business. He stated that he knew it was weak stuff and would not hurt him, and his wife declared he had done it to frighten her. Discharged with a caution.

THE Gem Dry Plate Company notify us that in order to conform with post-office regulations, their correct postal address is now 92a, Villiers Road, Cricklewood, London, N.W. The telegraphic address and telephone number of the company are Chemitype, London, and 2757 P.O., Hampstead.

PRINTING Stereo Negatives.—Mr. Theodore Brown writes in reference to our paragraph last week:—"You mention a system of printing stereoscopic negatives without involving the need for transportation, described by M. Fabre, in his 'Traité Pratique.' You say this would seem to be a novel means of printing at one operation, etc. May I venture to point out that there is nothing novel about this printing dodge, F. Drouin, another French writer, having fully described the method in his work, 'The Stereoscope and Stereoscopic Photography,' pages 169 and 170."

PHOTOGRAPHS by C. F. Inston.—The succession of house exhibitions, which have been arranged by the Liverpool Amateur Photographic Association, have at length arrived at that of Mr. C. F. Inston, or will do so to-morrow, September 1. The photographs, just over the hundred, are hand camera work in the majority of cases, and, it is to be hoped, will be visited by photographers within

reach of Liverpool. The rooms of the L.A.P.A., at 9, Eberle Street, Dale Street, where they are arranged, are open, from 10 to 6 (Saturdays 10 to 4), until September 15.

HOVE Camera Club.—We regret to record the death of Mr. W. H. Bone, the Hon. Secretary, who was accidentally drowned while bathing. Pending the appointment of his successor, Mr. Geo. W. King is acting as secretary, and all communications intended for the Society should be sent to him at 55, Western Road, Hove.

THE Henderson Award at the L. and P.—The last day for the receipt of papers in competition for the "Henderson Award" of £5, offered under the auspices of the London and Provincial Photographic Association, has been fixed for Friday next. The papers, which should be on a chemical or photo-chemical subject, should be sent to the secretary, Mr. H. C. Rapson, 13, Shaftesbury Road, Hornsey Rise, N.

DEATH of a Lady Tourist Photographer.—One of the most tragic of the holiday fatalities of the season occurred at Boscastle (Cornwall) last week. The victim, Miss E. M. Elcock, of Birmingham, was staying at Boscastle. Accompanied by a friend, Miss Elcock went in the morning on the cliff to Penally Point, a huge rock 200 feet in height. She had a camera with her, and when on the top of the cliff stood on a ledge of rock for the purpose of taking a photograph of her friend. With her back to the sea Miss Elcock made a false step and fell over the cliff, pitching on the rock, and falling into the old bathing pool. An alarm was raised and boats were quickly manned. On reaching the spot her dead body was found terribly cut. The camera was still in her hand.

PHOTOGRAPHING Fortifications.—A sergeant of the Royal Garrison Artillery, who are dismantling the fortifications of the Scilly Isles, noticed a foreigner photographing the Artillery appliances near the camp on Saturday last. The sergeant at once deprived the man of his camera and exposed the films to the light. The stranger could give no intelligible explanation of his presence, and spoke very little English, but after being searched was allowed to go free.

INCANDESCENT Mantles and the Gas Bill.—One of the most noticeable points in connection with the gas industry is the rapid increase in the use of the Welsbach mantle, which is having an effect upon the sales of gas hardly contemplated by gas companies when the great improvement in the mantle recently brought it into favour with the public. The "Society of Arts Journal" quotes from the report of the South Metropolitan Gas Company for the six months ended December last, in which it is stated that there was an increase in consumption of only 1.5 per cent., and the main cause of the smallness of the increase was attributed to the great saving to the consumer by the constantly increasing use of the Welsbach mantle. For the half year ended June 30, similar comparative shrinkage is shown. About 80 per cent. of the South Metropolitan Gas Company's consumers are using mantles, and it has been found that the consumption of gas is reduced, on the average, by about 21 per cent. The dividends of the gas companies will suffer, but they remain generous, and the saving in gas bills is appreciable. Moreover, the light given by the mantle is a great improvement. It may be noted that the convention controlling the price of thorium has this year reduced the price by about one half, with the result that for the time mantles will be plentiful and cheap. It is monazite sand from which the constituents of incandescent mantles (thorium 99 per cent. and cerium 1 per cent.) are obtained, and this sand has been mostly in the hands of a group of Continental firms known as the Thorium Convention. The South Metropolitan Gas Company, has, however, succeeded in purchasing a monazite property in North Carolina, which assures its supply of mantles at a reasonable price.

As regards the wear and tear of the incandescent mantles, "Iron Age" writes that it is usually found that illumination increases for a short period, after which a slow but steady fall sets in. The initial rise is credited to a gradual shaping of the mantle to the flame. The subsequent fall is attributed to two causes. One is that dust particles of silica are carried by the draft against the mantle, where they form, with the oxides, infusible silicates of low emissive power. The other, and more potent cause, is the gradual volatilization of the ceria, to which the incandescence is due. It is also found that the hygroscopic state of the atmosphere has a small but measurable influence on the luminosity of the mantle.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### TANQUERY IN THE ARGENTINE.

To the Editors.

Dear Sirs,—I have followed with some interest the developments of the free enlargement swindle as exposed in the columns of your paper, and I thought you might like to know that it has commenced operating in the Argentine Republic. I received among my letters this morning a communication and some printed matter from The Société Artistique de Portraits (A. Tanquery, Directeur), of 23, Rue de Hambourg, Paris, making similar offers to those which you have so often exposed. Apparently, however, they are trying something new, as one of the paragraphs reads (translated) more or less as follows:—

"Perhaps you have previously received from other firms similar offers to the one we make you, but have been unable to get the enlargement free, it having been necessary to buy a frame. This is not the case with our firm; the client is free to BUY THE FRAME WHERE HE LIKES." (The capitals are M. Tanquery's).

As I am rather curious to see where the swindle comes in, I have written to M. Tanquery, sending a photograph for which I have no use. If it results in anything new I will let you know.—Yours very truly,  
G. R. CLUTTERBUCK.

Moreno, 452.

Buenos Aires, Argentine Republic.

August 2, 1906.

We have no doubt of M. Tanquery's intention to collect money at a later stage of his relations with anybody foolish enough to do business with him. We shall be interested to hear of any new departure of his, but probably the old story of costly transport charges has lost none of its efficacy in his hands.—Eds. "B.J.P."

### A FLASH LAMP PATENT.

To the Editors.

Gentlemen,—In your issue of August 17, under the heading of "Patent News," particulars are published of a flashlight lamp, the charge being fired by means of a fulminating cap, this method of firing being claimed as a novelty by the applicant, a Japanese. Permit me to point out that although such a lamp is unknown on the British market, I have used for some time an American lamp of this pattern, and as it may interest you, I am forwarding it for your inspection, so that you can try how remarkably efficient it is, and also see that it was patented in the United States in 1901.

The lamp is so safe and superior to anything of the kind that I have seen before, that I had every confidence in acceding to the request of the American manufacturers to introduce it to the notice of a British firm, so that before publication of the Japanese patent above mentioned, I had communicated with Messrs. Houghtons, and as they doubtless will place it on the market here, in their interests I think it advisable to prove to you by a personal inspection of the lamp and the patent date on same, that the new application is not patentable, and, therefore, if Messrs. Houghton place it on the market they will not be infringing any rights in so doing.

I may add I am not interested in any way in the lamp.—Yours truly,  
H. J. MALLABAR.

59, Deane Road, Liverpool.

August 24, 1906.

[The lamp mentioned in our issue of the 17th inst. differed somewhat from that sent to us by our correspondent, but its construction embodied so little of novelty that we did not consider a lengthy reference to it necessary. As for the American lamp before us, it is a remarkably simple instrument, and one, as we have convinced ourselves, which is efficient in practice. We can quite confirm our correspondent's good opinion of it.—Eds., B.J.P.]

### TITLES ON NEGATIVES.

To the Editors.

Gentlemen,—Having noted the somewhat frequent queries in "Correspondence" column for a simple method of titling negatives postcard printing, I thought the following method might be service:—First obtain a piece of transparent tissue or tracing paper—that generally used in the manufacture of tissue print protective envelopes is as good as anything—place same over a piece of clean white paper, on which lines have been ruled, so that lines show through sufficiently to act as a guide to the lettering, then pen write or print the desired title with a No. 1 brush and any opaque colour—Indian red is very suitable—and allow to dry. A light retouching medium is then applied to the part of negative where title is to go, title placed carefully on prepared space, painted printed side down, and after being pressed into contact, another fair liberal coating of medium applied, which will make the paper quite transparent and protect the whole thing. With a little practice lettering can be done very neatly and effectively, and if the superfluous paper is trimmed off before applying to negative nothing shows finished print but the lettering. I may add that the medium may be applied with a brush, both before and after placing title, by rubbing on in usual way, there would be insufficient to make paper properly transparent.—Yours faithfully,  
W. SHENTON

Grove House, 282, Bury New Road, Higher Broughton, Manchester  
August 26, 1906.

### SALONICAL PROBLEMS FOR THE SILLY SEASON.

To the Editors.

Gentlemen,—While the great dailies are hearing both sides of such great questions as "Are We Too Squeamish?" or "Is Existence Wrong?" I notice a paragraph in the "Amateur Photographer" which appears to contain all the proper elements of a newspaper discussion. True, its theme is the well-worn one of Salon at Royal, but there are added touches of imagination or fantasy, which give the colour of romance to the prosaic business of receiving pictures for, and for opening the two exhibitions. These dates are

	Receiving Day.		Opening Day.
Salon .....	September 3*	.....	September 14
Royal .....	September 6	.....	September 20

\* Photographs are usually judged the next day—i.e., September 4.

This arrangement of dates allows an exhibitor whose work is checked at the Salon to offer it to the Royal, a course to which the Salon presumably has not the smallest objection. In fact, there is a note of jubilation in your contemporary's picture of a procession of cabs (hansom, it is to be hoped) making its way from Pall Mall to Regent Street a year or two ago. But what the Salon evidently does object to is that the same photographs should be offered and accepted at each exhibition, to "check" which it ruled that "Pictures sent for exhibition to any other exhibition open in London at the same period are liable also to be disqualified." Your contemporary remarks: "There is ample time between the opening of the two exhibitions to ascertain whether the author of a picture accepted at the Salon has sent a duplicate to the Royal, thus causing its rejection, even though its actual merits would have secured its being hung." I ask:—

1. How will the Salon committee disqualify on this account, sixteen days before the Royal opens?
2. Or is the Royal acting as information bureau to the Salon?
3. Or is it second sight?
4. Or bluff?

—Yours very truly,

NEMO.

[We can only say that we are informed by Mr. J. McIntosh, the secretary of the Royal Photographic Society, that under no circumstances are particulars of the entries to the exhibition accessible. From what other source, knowledge of an exhibitor's submission of a picture to the R.P.S. can be obtained, we are unable to say.—Eds. "B.J.P."]

## Answers to Correspondents.

\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

G. W. Gibson, High Street, Coldstream. Photograph of C. F. Blyth, King of the Yetholm Gypsies, Riding on a Donkey.

C. Lee, Market Oyster Stores, Warrington. Photograph of a Freak Crab.

A. Lafosse, 12, Oxford Street, Manchester. Two Photographs of Mr. Louis De Rougemont.

A. Shrapnell, Bell Green, Coventry. Nine Photographs of Views of the Daimler Motor Company's Works. Photograph (Combination) of a Shamrock Leaf Containing a Motor Car in each of the Three Portions of the Leaf together with Royalty.

J. E. Reeves, 48, Hermit Road, Canning Town, London. Photograph of the West Ham United Football Club.

**FACING PHOTOGRAPHS WITH CELLULOID.**—As I am not aware of having seen it noted anywhere the method of facing any kind of photograph with thin celluloid, will you please say how it is done or mention any book or paper from which such information can be had?—CELLULOID.

The prints are soaked in spirit and subjected with the sheet of celluloid to a hot pressure. If you write to Jonathan Fallowfield, 146, Charing Cross Road, London, W., for his catalogue of photo button apparatus you will obtain particulars of a suitable press, or one of the presses of the Adhesive Dry Mounting Company, Fetter Lane, E.C., would answer admirably for the purpose.

**GLOSSY BROMIDES.**—Will you kindly help me in the following? I am printing in bromide paper (glossy), and wish to know how I can get a good burnish on the prints without using a burnisher.—S. H. DAWSON.

The gloss of bromide prints may be increased by squeegeeing them, after washing and aluming, on to a ferrotype or glass plate, that has been previously rubbed over with French chalk. If the prints are not alumed it is best to let them dry, and then re-wet them thoroughly before squeegeeing on to the plate, otherwise there may be a danger of their sticking.

**STUDIO QUERY.**—I have a studio, or a glass house, which I intend to use as such. Unfortunately it is only 5ft. 6in. wide, the length is 21ft.; 13ft. of that has a roof 10ft. high, sloping down (to side light) to 8ft.; the remaining 8ft. in length has roof 7ft. high, sloping down (to side light) to 6ft. The low end I was thinking of darkening with blinds and standing camera in the tall end for sitter. I shall be greatly obliged if you will tell me the best way to arrange my lighting. I was thinking of having blinds on rollers, or would you have curtains run on wires? How many should I require, and which way should they run? Also what colour should they be? There is 13ft. of side light,

4ft. 6in. high, starting 3ft. 6in. from ground, 13ft. length of top light, 6ft. wide. The glass is Hartley's rolled plate. I get practically a north light. The shadow side of sitter is a brick wall. What colour would be the best to paint it with?—GRATEFUL.

The studio will certainly be very narrow for portraiture, but the way you propose to use it will be the best. You might stop off all the light from the 8ft. length, as with such a narrow studio that will not be required. Three feet at the sitter's end, top and sides, may also be stopped off. The top blinds may be on rollers, and curtains may be used for the sides. As you have a north light, pale green or medium blue will be a suitable colour for them. The wall had best be coloured of a rather pale green or a blue.

**PHOTOGRAPHING MOTOR CARS.**—I would be greatly obliged by the assistance of your advice in the following matters:—I contemplate building a studio, in which to photograph motor cars and parts, from whole-plate size upwards. The over-all measurement of the largest car would be approximately 17ft. Will you therefore kindly suggest a suitable size for this studio, position, form of lighting (artificial and daylight), blinds, reflectors, colour, etc.? At the present time I am photographing the cars out doors, but am troubled with reflection on the highly polished surface of the coach work and heavy shadows underneath the cars, and wish to arrange my studio lighting so as to avoid this as far as possible.—STUDIO.

It seems to us that you will require a studio from 25ft. to 30ft. wide to evenly light the cars when photographed broadside on. Its length must very much depend upon the focus of the lenses you employ, but about the same length as the width will suffice, or a little less. As to the form, either the ridge roof or lean-to may be adopted; perhaps, on the whole, the latter will be the better, as then you will be able to light from either side without having to shift the cars. For blinds, we should suggest a medium green or dark blue. For artificial light two enclosed arc electric lights should be suitable. We should have surmised that you would be quite successful in photographing the cars out of doors if you had a light awning over them to subdue the light. If you could arrange to have the cars before the wood is polished you would not be troubled by the reflections from the polish.

**PORTABLE ARTIFICIAL LIGHT.**—1. We are a firm of travelling photographers, with a studio on wheels, and wish to run the stamp and midget business during the winter. Our difficulty is to find a suitable illuminant. Flashlight is too smoky, or expensive. We could, perhaps, get the gas laid on from the main (we understand that a special lighting arrangement with many burners has to be used), or we could carry cylinders. Do you think acetylene gas would be practicable? We require a light strong enough to correctly expose a special rapid plate in about three seconds. 2. Can you give us address of firm supplying comic cartoons? The sitter places his head through a hole, and when photograph is finished he is shown riding a miniature donkey, or something of that description.—STAMPS.

1. For the midget outfit apply to Sharp and Hitchmough, Dale Street, Liverpool, or to Jonathan Fallowfield, 146, Charing Cross Road, London, W. Acetylene would be certainly the most suitable light. If you address R. J. Moss and Sons, 98, Snowhill, Birmingham, or Thorne and Hoddle, Victoria Street, London, S.W., they will be able to supply you with a generator, purifier, and lamp for the purpose. 2. Sharp and Hitchmough, Liverpool.

**PHOTOGRAPHY IN CANADA.**—1. Would be glad to know if there is any prospects in Canada for an operator and retoucher. 2. What pay do they give? and is there any paper published?—ANXIOUS.

We can only say that the general prospects are very good indeed in Canada, and that for those who can rough it for a few years, and can start over there with, say, £100, there is every likelihood of their doing well. Probably a good deal of business might be done by a couple of men prepared to travel through the North-West with their own outfit. 2. "The St. Louis and

Canadian Photographer," edited by Tony O. Babb, 3210, Locust Street, St. Louis, U.S.A.

**SOLAR PROCESS.**—I shall be extremely obliged if you would be so kind as to let me know by inserting in the next issue of your paper, as a question, the process of coating solar paper.—**ENLARGER.**

The following process given in our pages some time ago has been recommended for the process:—Milk, 2 oz.; glacial acetic acid,  $\frac{3}{4}$  oz.; mix, stir well, and filter, and add to the filtrate:—Potass iodide, 140 grs.; potass bromide, 34 grs. Paint the solution over the paper, and dry as quickly as possible. The prepared can either be floated on the following bath, or it may be painted on:—Silver nitrate, 40 grs.; distilled water, 10z.; glacial acetic acid, 1 drachm. The paper must be exposed wet. It is 1-3rd to 1-4th the speed of bromide paper. The developer is:—Pyro, 3 grs.; water, 1 oz.; glacial acetic acid, 40 minims; 10 per cent. citric acid solution, 4 drops.

**BACKGROUND PAINTER.**—Can you give me the address or addresses of any background painters in London? Not an agent.—**PHOTOGRAPHER.**

J. F. Bull, of 54, Great Queen Street, London, W.C.

**ISLAND.**—Better get "Press Photography" (Dawbarn and Ward, 1s.), wherein you will find advice on the points you raise. We should advise you also to have a course of postal lessons in Press photography from the Practical Correspondence College, Thanet House, 231, Strand, W.C.

**TITLES ON POSTCARDS.**—You gave some useful information a short time ago for naming postcards by copying printed type on stripping films. Are these stripping films commercially obtainable, and can they be procured giving strong contrasting negatives so that the lettering can be firm on a white ground? I presume they are cut up and fixed to the bottom of the negative.—**T. V. B.**

The titles are photographed on to an ordinary gelatine plate—a "process" or photo-mechanical" plate for preference—and the film stripped off with hydrofluoric acid, as commonly used for this purpose. You will find the stripping formulæ in the "Almanac."

**REPAIRING DISHES.**—Will you kindly inform me what is the best substance to use in repairing papier-mâché dishes of large size? They now seem to be made with corner pieces, which speedily fall off, and then the whole thing rapidly comes to pieces. Also what is the black coating material for the trays?—**T. V. B.**

The best thing for the purpose is marine glue, or Prout's elastic glue, which is to be had at most shops where shoemakers' material is sold. Directions for use are enclosed with the cement. After the parts of the trays have been repaired, they should be given one or two coatings of Brunswick black, which may be had at the oil shops.

**PHOTOGRAPHING PLATE.**—I have been asked to photograph a challenge shield. It is of silver (polished), with a lot of embossed work and engraving, mounted upon walnut, and surrounded by medallions for names of winners, etc. I would be glad if you would let me know in B.J. what would be the best way of dulling the silver surface without injuring same, so that I could get a good photograph of it. Is there anything I could work into the engraving (the winners' names, etc.) so as to bring it out distinctly, something that would brush out clean afterwards?—**SHIELD.**

The best way will be to get a copper-plate printer to ink up the lettering in the same way as he inks up a copper or steel plate for printing, using what is known as cold ink for the purpose. Then the bright surfaces of the metal should be dulled by dabbing it over with a ball of glazier's putty. Then, if care be taken in the lighting that there are no reflections from the metal in the direction of the lens, there will be no difficulty in getting a good copy. After the copy has been obtained the ink can be removed with benzol, and the putty cleaned off with the rectified turpentine.

**VARIOUS.**—(1) What is a good formula for the toning of bromide to sepia colour, now getting so popular? (2) Where can M. H. P. Robinson's book be obtained, "The Studio, and What to Do With It," and what is the price of it? (3) What color blinds are most suitable for studio with direct sunlight on glass until 12 o'clock? After this time the side glass is in shadow the remainder of the day. Are the blinds best rollers or on wire, to knock along? What would be the name of the material to purchase it? Can you say how the enclosed print is lighted? It appears to be strong side light, with soft shadows.—**BROMIDES.**

The following, from the current ALMANAC, is an excellent formula:—

A. Ammonium bromide .....	300 grs.	35 gms.
Potassium ferricyanide .....	300 grs.	35 gms.
Water .....	20 ozs.	1000 c.c.s.
B. Sodium sulphide (pure) .....	100 grs.	12 gms.
Water .....	20 ozs.	1000 c.c.s.

Bleach the fixed and washed print in A solution. Wash for few minutes in water and then immerse in B solution until toned. The print is then well washed and dried. (2) We have an idea that it is out of print. If you write Messrs. Dawbarn and Ward, 6, Farringdon Avenue, London, E.C., they will tell you if it can be obtained. (3) As the sun is only on the side of the studio we should say that curtains, running on a rod or a wire, would be the most convenient, and, at the same time, the best. For the material we should suggest a blue serge. The portrait enclosed is lighted by a side light, the shadows being softened by a subdued front light or by reflectors.

**FLASHLIGHT.**—I have to take a flashlight photograph of a party (between fifty and sixty people) at dinner in a room about 70ft. long and 30ft. wide, so should be glad of your advice. (1) What kind of apparatus to use to flash the powder, and would a lamp be necessary? (2) What kind of powder to use, and how much would be required for the exposure? (3) Where would you advise placing the flashlight apparatus?—**WALES.**

(1) A lamp of the long tray pattern, such as the Weiss, is certainly the best, but we should say you will find a train of powder laid in a shallow trough (a piece of sheet iron bent to the shape), to meet your requirements. (2) One of the newer flash powders, such as the "Agfa" (Charles Zimmermann and Co.). For a room of the size you name a quarter to half an ounce should suffice. (3) The lamp should be placed about 10ft. or 12ft. up, a little to the right or left, and at the bottom of the tables—i.e., the end farthest from the chairman.

**G. G.**—The usual plan is to squeegee the glass or ferrotype plate, and to use a burnisher. If you will say why you have failed with the former method, and tell us what is your trouble we will try to assist you.

**D. B.**—We believe that, except in the case of dyes, which are used with ammonia, no difference will be found between the wet and dry plates, but we cannot say that we have made comparisons.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Some of the difficulties in the way of a certification scheme for photographic assistants is the subject of an article. (P. 702.)

The clever skit of "Judy" upon the free portrait swindles has been reprinted by the Professional Photographers' Association, and reproduced on p. 707.

Mr. F. C. Tilney, in a criticism of the photographs of Mrs. Julia Cameron now being exhibited at these offices, reviews Mrs. Cameron's pioneer work in photographic portraiture. (P. 704.)

The precautions needed in the photography of articles of ornament, furniture, legal documents, etc., are related by an American photographer whose own business has been in these branches. (P. 705.)

Interesting sidelights on the recently proposed international exhibition of photography in Paris are cast by some correspondence addressed to Dr. Hutchinson. (P. 700.)

A continuation of the experiments of Mr. N. S. Amstutz on the properties of half-tone blocks is given on p. 708.

Captain Lascelles Davidson has patented a system of colour-photography from one negative. The patents of the week also include a reflecting stereoscope. (P. 711.)

Herr Worel has recorded his good opinion of the bleach-out colour P.O.P. of Dr. Smith. (P. 705.)

The exhibition season opens with the Royal Cornwall Polytechnic Society at Falmouth. At Liverpool Mr. C. F. Inston is at present showing a collection of his photographs. (P. 713.)

The programme of lectures to be delivered during the Royal Photographic Society's Exhibition at the New Gallery is given on page 717.

The members' dinner of the R.P.S. is to be held at the Holborn Restaurant on September 18. (P. 717.)

Mr. E. L. White has resigned from the managing-directorship of the Photochrom Company. (P. 718.)

## EX CATHEDRA

### The Proposed Paris Exhibition.

An ominous silence has reigned for some months as regards the great international photographic exhibition to have been held in Paris during the present autumn. When we assumed an agnostic attitude respecting its claims to secure support from photographers and the photographic trade in this country, we were accused of hostility by M. Gastine, the promoter, but later events seem to suggest that we were right in discountenancing a scheme of which we were able to hear nothing satisfactory in quarters in Paris which we had reason to believe were well informed, and honestly acting for the public interest in their attitude towards the proposed exhibition. From the note which we publish in another column it would certainly seem that the promoters of the exhibition were not merely ill-advised and foolishly sanguine, but also unbusinesslike to a degree which suggests imposture. The letter addressed to Dr. Hutchinson relating to the exhibition of some three-colour lantern slides, has a very nasty look of getting money by false pretences about it, and we have also before us some letters which give an account of attempts made to find M. Gastine at either of the two addresses from which he wrote. A Monsieur Charpentier, who was alleged to be associated with M. Gastine in the promotion of the exhibition, wrote from a block in Avenue de la Motte Picquet, but had left his flat there without leaving his address. Enquiry at the Grand Palais des Champs Elysées, which was represented as the headquarters of the exhibition, elicited the fact that letters and parcels had been addressed there to M. Gastine on the understanding that an office was shortly to be opened there for them. Yet it could not be ascertained that an office had been opened. The concierge at the Grand Palais had been told by M. Gastine to send letters to his office in the Avenue de la Motte Picquet, the premises which were afterwards found empty. With these facts before us, we cannot but feel that a good deal of explanation on the part of M. Gastine will be needed to show that the exhibition was honestly promoted.

### The Measurement of Focal Length.

Methods of measuring focal length are plentiful, and fresh ones are continually being suggested, while forgotten ones are always being revived. We are doubtful whether the method recently put forward by M. Masson should be classed as a novelty or a revival; but it is so simple as to be well worth notice, even though its application is limited to symmetrical doublets. If we take such a doublet and focus with it upon a distant object, then remove the front lens and rack out to re-focus, the difference between the two extensions of the camera is the true focal length of the complete doublet. No apparatus is required beyond a camera with sufficient ex-

tension and a suitable measure, and the test is easily made in a couple of minutes. The drawback is that the two components of the doublet must be of exactly the same focal length, but in many doublets in common use this condition is fulfilled with sufficient accuracy. If there is any doubt on this point the lenses can be reversed, front for back, and the test repeated. If there is no appreciable difference in the results obtained we can rest assured that the doublet is as nearly as possible symmetrical, and that we have determined its focal length with a very considerable degree of accuracy. If the results differ, the true focal length must be a dimension between the two arrived at, and if the difference is only a small fraction of an inch, the mean between the two determinations will be accurate enough for all practical purposes. It may be as well to add that a back focussing camera is not essential. Any kind of camera will serve, provided it will extend far enough. We are inclined to think that this method is not only simpler, but far more accurate than many of those so frequently advocated.

\* \* \*

#### A Factor Affecting Intensification.

During some recent experiments on intensification we noted a fact that seems to be very little considered in connection with the subject of intensification in general. All the more important intensification processes depend on the reinforcement of the image by a metal or metallic compound; this additional material being reduced by the silver forming the original image from the solution employed. Thus in the mercury and ferrous oxalate method the image is reinforced by mercury; in the chromium process by a chromium compound, and in the uranium process by a uranium compound. The mechanism of these processes varies, and the effect we noted may not exist with all, but from its nature it may very reasonably be suspected. Our experiments were conducted with the chromium method, and this we found to be a powerful method in the case of a clean image, but a comparatively weak one with an image that included pyro stain. One application of the process is most effective on an image developed with hydroquinone, metol-hydroquinone, or non-staining pyro-soda, but often the process has to be repeated to gain sufficient density if the original image has been developed with the ordinary pyro-soda formulæ that mostly give more or less stain. It would seem evident that the organic deposit present in such instances clogs the image,

and so either obstructs the deposition of the chromium compound, or hinders the chemical action that causes deposition. If this takes place with the chromium process it would seem highly probable that a similar effect must be produced with the mercury and analogous processes, this point should be investigated and tested. It is obvious that factors expressing the amount of density gained by any process of intensification are of little value if the result differs with the cleanliness of the original image and the method by which that image is produced is not stated. Therefore we venture to advise the mention of the original developer used, wherever measured results of intensification are published.

#### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION AND ASSISTANTS' CERTIFICATES.

The discussion on the P.P.A. and Assistants' Certificates which has been going on for some weeks past in our correspondence columns, has been interesting, and, to an extent, has served a useful purpose in throwing some sidelight on the photographic business as carried on in some places. All sides having now had ample opportunity of expressing their views, the time has arrived, it seems to us, when a discussion should be brought to a close for the present.

There is no question that if an employer, when selecting an assistant from a number of applicants, could ask for the production of certificates of a certain degree of proficiency in the assistants' work, issued by some recognised authority, it would be a great saving of time to the employer, and should be, in the end, to the benefit of the employees. The question is, upon what conditions should the certificates be granted, and who is the authority to grant them? The P.P.A., through its committee, which is composed of thoroughly practical professional photographers, would unquestionably be a suitable body. Yet it is difficult to see how it could do so satisfactorily, unless it put the candidate through a practical examination in the different branches of the art in which they desire to have certificates. This seems to us the only way in which anything could be satisfactorily undertaken. When, for instance, a candidate for an operator's certificate is given

#### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

sitter to deal with in a strange studio, a committee of two or three experienced portraitists can quickly sum up his abilities as an operator in portraiture. Similar practical tests might also be applied in other branches of the profession, and certificates granted under these conditions should certainly be valuable to those who obtained them, and they would be some guarantee of capability to those desirous of engaging their services. Yet, laudable as these measures are, we must yet confess that we cannot discern a prospect, at present, of their being carried out. The P.P.A., commendable as are its objects, has, up to the present, received but scant support from the profession generally, though the annual subscription is quite a nominal one. The offices are all honorary, and it cannot be expected that the committee can devote, personally, the necessary time from their own business to the practical examination of candidates for certificates, even if a small fee were charged for the examination. If the Association received better support, its funds would be larger and, possibly, something in the direction indicated might be done. However, as things are at present it seems to be out of the question altogether.

Comments have been made, during the discussion, by some writers as to the status of many of the photographers who have become members of the P.P.A., and there are some grounds for them it may be admitted. But it must be remembered that the P.P.A. is a young body. When it was established all professionals were eligible and invited to join, and that is the case still. Such conditions of membership—inevitable in almost every new body which is at all broad in its aims and objects—will gradually be modified as time goes on, with the result that admission to the Association will become stricter than is at present the case. Yet such a change towards a higher status is necessarily a very slow one, and, in the meantime, perhaps the best comment which can be made on the remarks of those who complain of "backyard studio" men in the P.P.A., is that they should labour to keep this class in the minority. Yet the status of even a considerable section of members of the P.P.A. does not affect the question of certificates, for no one will question the ability of the Association to make up a competent examining committee should one be required.

Yet it seems to us that no scheme of certification by examination, any more than the present one of investigating references to past employers, can entirely suit the wide range of circumstances to be found in photography. A certificate may be of the greatest assistance in labelling an operator or printer, but it cannot entirely supersede the investigation of the individual's record. It is no doubt true, as some have said, that advertisements have been inserted for a first-class operator, and after an en-

gagement made by correspondence the successful applicant finds, when he gets to the place, that the business, instead of being first class is only a third or fourth rate one where only very mediocre work is done. This is, naturally, very disappointing to him, since the value of a reference from such a place in the event of his applying for an engagement elsewhere is very small, and also an employer in giving a reference is apt to gauge the quality of an assistant's work by his own, and that, if one may judge from the specimens to be seen in show cases and shop windows in many small country towns, is very poor indeed.

Employers often complain that very incompetent men apply for situations; that is not at all surprising, seeing that with dry plates and ready prepared papers there is very little to learn so far as the production of fairly good negatives and making prints from them are concerned, yet that is quite a different thing from being a good operator. In the studio all this is really of minor importance. There, artistic ability in posing and lighting, together with tact in dealing with sitters, is the chief consideration, and it is these qualifications which so many who style themselves first-rate operators so sadly lack. In the wet collodion days there was so much more to be learnt than there is at present, but there were men then who could not produce an artistic picture, and some of these men are still unable to do so even with dry plates.

Complaints are sometimes made by employers, when an assistant has been engaged, that he is incapable of producing work equal to the specimens he submitted when applying for the post, and suspicion is expressed that they were not his own work at all. In some instances that may possibly be the case, but it must not be forgotten that when a man is taking, say, a dozen to twenty negatives a week, it would be strange indeed if he did not get one or two presentable ones now and then, if only by a "fluke," and from these he would undoubtedly select specimens of his work.

There is no question, as our advertisement columns each week show, that, at the present time, there is a large number of assistants out of employ. Yet we learn from high-class houses that, when they have to make a change, they have great difficulty in obtaining a first-class artistic operator of gentlemanly manners, with the necessary tact and skill to deal with their high-class clientèle, although they pay more than double the salaries asked by so many, who style themselves first-class operators.

With regard to the recent discussion, as a matter of fact, things remain very much as they were at the beginning of it. The suggestions that have been thrown out are, many of them, good, though the carrying of them out, under the existing condition of things, is, unfortunately, impracticable.

**SHEFFIELD Photographic Society.**—An agreement has been made between this society, the Nottingham Camera Club, and the Leicester and Leicestershire Photographic Society, whereby the forthcoming exhibitions of the respective societies will follow each other, pictures being conveyed from one exhibition to the other free of cost to the several exhibitors. A collection of photographic portraiture, by Herr R. Dührkoop, of Hamburg, brought together by the **BRITISH JOURNAL OF PHOTOGRAPHY**, will be shown at the Sheffield and Leicester exhibitions.

**Messrs. Methuen** are publishing photographic copies of each of the great Folios of Shakespeare. Though facsimile reprints from the First Folio have been printed from time to time, there have been none, before the present edition, of the Second, Third, and Fourth. To scholars and lovers of Shakespeare the next best thing to possessing an original set of the Four Folios, at a cost of some £7,000, is to have the facsimile for something less than £4 4s. Messrs. Methuen have already issued the Third and Fourth Folios, and these will soon be followed by the Second.

## THE EXHIBITION OF PHOTOGRAPHS BY THE LATE MRS. JULIA CAMERON AND H. H. HAY CAMERON.

THE present exhibition at the gallery of the BRITISH JOURNAL OF PHOTOGRAPHY is of particular and absorbing interest. The visitor will probably leave it with mixed feelings, nevertheless. After the lapse of more than a third of a century, during which time the development of photography has entirely altered all but its bare principles, the portraits of this remarkably clever photographer win from us the same plaudits that we should pay to a fine work in an exhibition to-day—a work produced with apparatus and materials of adaptability and convenience undreamt of in Mrs. Cameron's day. Forty years ago Sir John Herschel wrote:—"This last batch of your photographs is indeed wonderful, and wonderful in two distinct lines of perfection." In many respects the critic who is faced again by these monumental portraits, might repeat the dictum of the great Sir John, and not feel himself to be stretching a point.

Mrs. Cameron appears to have received encouragement in liberal measure from the great lights of her day, and that fact alone would afford her efforts an impetus denied to modern workers, who feel already the pinch of competition, and whose results are no longer regarded as a kind of magical juggling with the forces of nature. Mrs. Cameron was practically alone. She certainly was a pioneer, and the eyes of scientific enthusiasts were turned towards her. It is not to be wondered at that she "felt her position," as the saying goes. To run to her marital partner with each new negative all adrip with nitrate of silver and await his "enthusiastic applause" is a thing that many a beginner has done since that day when photographers were few and far between. Still Mrs. Cameron admits to a weak spot in the matter of fame:—"I must confess that when those whose judgment I revered have valued and praised my works, my heart has leapt up like a rainbow in the sky," which is rather a bad hash of the immortal lines, since Wordsworth never accused a rainbow of leaping up; but we know full well what the lady wished to express.

The fact of her being a pioneer, however, may be regarded in one respect as having unfortunate results. Lured as she was into the unexplored tracts of picture-making by photography, it was not possible for her to make that artistic selection of subject matter which comes by inherited experience to workers in these times. Everything must be tried by her wonderful camera, and as a consequence much was tried that to-day, tried again, is found wanting. In view of such a work as "The Three Fishers" we can do no more than admire the ingenuity with which the *mise en scène* is prepared. The elaboration of the property fireplace is appalling, and the sweeping together of pots, pans and other utensils is harmfully obvious. What, exactly, the feebly-grouped quartette are doing, and which of them are the three fishers, if any, is not at all clear, and therefore the work must be said to fail in story-telling—presumably its chief mission. It represents a fisherman leaning against a wall and sheltering a boy dressed in a very commonplace "sailor's suit." These are to the right of the composition. To the left a little girl kneels up in prayer to a woman whose head is bowed. It all must have meant exemplary painstaking and patience in those days of long exposures; but its result leaves one quite cold. Possibly what it should convey is the sentiment that men must work and women must weep—only, as it happens, the man is not working—at least, not at his trade—and the woman not obviously weeping.

Again, in "The Five Foolish Virgins," the passion for narrative that has been the downfall of all pictorial photo-

graphers, has led this talented one into misfortune. On the face of it, these five young ladies could not by any chance be thought to resemble what five Oriental wenches at a wedding ceremony must have looked like two thousand years ago. So far realism is hopelessly out of the question, and whatever may remain in a sort of symbolic idea of the parable is much too grossly presented by these five posing ladies with their hair down for the occasion. It is a dismal group, with a tit strangely but unintentionally fit.

So also in the "Nestling Angel." If there are such things as cameras are not for them in this world, and there will probably be but few amongst the angels hereafter. This figure is even less an earthly child. Pencil and paint may portray monsters and other things not indigenous to this planet; but a monster that is photographed necessarily proclaims itself a bogus affair. This is one of a sentimental kind, draped below the breast so as to eliminate all that anatomy missing in the genus *cherubim* common to ecclesiastical embellishments. Two fowl's wings rescued from the kitchen, are arranged to droop over the shoulders from behind the head of the child; result, a nestling angel. In a lesser degree "St. John the Baptist," "The Kiss of Peace," and others, court also that wholesome flippancy which is the only criticism of things that miss their mark. If such things have great intrinsic beauty their misjudged motive cannot hurt them. Thus, for all the costumery of Lancelot and Guinevere, and the expressions that seem to miss altogether the strenuousness of the Arthurian legend, it must be admitted that, simply as two figures, these are beautifully posed. So with "The Angel in the House," where the lighting and modelling are extremely good. This lovely subject would certainly meet with honours in an exhibition of modern work. "The May Queen" is a rustic in deportment; but as a rustic, and not as an embodiment of a Tennysonian idea, she is charming. But of King Arthur there must be few who could wax enthusiastic. He is entirely lacking in the nobility his character demands. His awful hand drawing a sword; his nineteenth century guard's helmet, and all the rest of it, prove at once the height of Mrs. Cameron's sanguineness and the shallowness of her experience in the matter of those artistic possibilities of photography which she thought so great; but which have since proved to be none.

Where she was great was in her heads from life, taken simply for their own sakes and without pictorial trivialities, such as entailed upon her long-suffering friend the holding of "my poker as his sceptre." In her portraits of Carlyle she has done everlasting work. The strength and subtlety of these mainly achievements, and particularly of the full-face version, are beyond praise. Lighting so forceful has seldom, if ever, been so eloquent of the character of the subject, nor sacrificed so infinitesimally the tender half-tones by which modelling, likeness, and completeness of effect are secured.

Her Tennyson is softer in treatment; but no less strong. It is the philosopher of "In Memoriam" rather than the poet of "The Idylls." Introspective and remote in his bearing, he seems to have paused in one of his lonely walks, bending his head as he pursues his train of thought. Joachim appears as a young man without a beard. The Joachim head is the only one of the series where the definition is quite sharp. In this particular Mrs. Cameron was more remarkably a pioneer than in any other respect. Her son gives it that this diffusion was "a fluke"; but it is surely no fluke to recognise a pleasing

circumstance when it comes in the way. She herself says that when focussing and coming to something which to my eye was very beautiful, I stopped there instead of screwing on the lens." What more deliberate and artistic selection could possibly be? Once seen always secured! That is scarcely fluking it shows more than anything else the amount of original taste and independent methods which together made up her talent. She earned, for this little trick, only the opprobrium of the photographic critic of that day. But what mountains of credit are due to her for bringing about by extemporisation, the very quantity that fashion followers now attain at the cost of a Dalmeyer-Bergheim lens, and with a molehill of credit!

Interesting as one of the finest likenesses of the sitter is her Darwin, though pictorially it is unpretentious, as Le himself was. Compare this with the Joachim, which has the air of an appearance in public about it. The wild and unkempt Herschel has a timorousness of eye and mouth bespeaking that humility which often is found in such scientific giants as Darwin and he himself were. As a head "Longfellow" is fine; but the attitude is posey. His hand, which looks small, is too near his face, and is weakly held in the folds of what seem to be quasi-classic draperies. These, and the clothes in most of the portraits, are so scantily illuminated, that the heads, collars, and shirt-fronts are somewhat harshly cut out in tone. Even Joachim's fiddle is suppressed in all but its high-lights.

Browning wears the same sham toga as does Longfellow. It was Mrs. Cameron's handiest way of investing a poet in romance. His ordinary clothes weren't good enough for him. The wonder is that such a man as Browning could submit. Three of his fingers make an odd appearance over the lower margin of the

picture, and would have been much better trimmed off. G. F. Watts is robed in a loosely-fitting wrapper, the heavy folds of which are fussy and disturbing.

In these heads, notwithstanding such minor drawbacks, Mrs. Cameron reached her highest point of merit, and became great. A few beautiful ladies' heads, too, will maintain her reputation. Perhaps "Zoe" is the finest in posing and general style of presentation. It is said she was somebody's cook whom the photographer stopped in the street and asked for a sitting. She looks more sadly and wistfully beautiful than the generality of cooks, to be sure. "Christabel" is also a lovely head, full of charms of the simple and unaffected kind. In "Mary Mother" the photographer has evidently been thinking of the Madonnas of the Carlo Dolci type; but the classic beauty of this head, and the hard and stony method of its treatment make it much more fit for a title from antiquity. Of a different style the portrait of Miss Ellen Terry makes a decorative display of dark and light tones that is a triumph. It is an irresistible portrait of an irresistible subject, and is one of the loveliest works in the gallery.

Mrs. Cameron's son is the Henry Herschel Hay Cameron, whose works are better known to us of this generation. A dozen or so excellent portraits by him show how good a thing it is for a photographer to have an artistic mother. He, also, has been fortunate in securing the portraits of many men and women of note. The Archbishop of Canterbury, G. F. Watts, Tennyson, and Browning, each of whom have signed their prints, Sir Henry Irving as "Beckett," Lord Roberts, and others of less note are included in his contribution, and supplement the value and interest of this exhibition.

F. C. TILNEY.

## FOREIGN NOTES AND NEWS.

### A Stand for the Pocket Spectroscope.

DR. F. LOWE, of the firm of Carl Zeiss, Jena, has designed a small piece of apparatus to permit of the easier and more convenient use of the pocket spectroscope in labora-

small glass vessels before the instrument, the stand shown in the figure has been designed. It consists of the wooden standard G, provided with a metal table piece, in which the spectroscope rests and against which the test tube is firmly pressed. It is held firmly in place by the piece, W, and the screw, K. The adjustments of the test tube holder permit of the tube being moved up and down and sideways, and the reflector, S, provides for the illumination of the comparison prism, in case the spectroscope is provided with this latter.

### A—Two-colour Printing Process.

The text of a German patent, that of Johann Karl Henberger, which is published in the current issue of "Photographische Industrie," forms another indication of the growing desire to produce simplified modes of obtaining colour prints. Though Herr Henberger uses only one paper support, his *modus operandi* leaves much to be desired, and the two-colour basis of the process excludes the reproduction of a wide range of colours. The process consists in coating an ordinary piece of silver chloride printing paper with a film of indiarubber, and to this applying a coat of gelatine. The negative to be printed yellow is made reversed, laid on the gelatine film of the paper, and exposure made as for silver paper. The print is washed in cold water for about half an hour, and is then given its yellow colour without drying by means of a 25 per cent. aqueous ammonia solution. The yellowing takes place through the uncoated paper (the back of the print), the print being fixed in frame and protected at the edges with strips of paper while the ammonia is applied. The action takes place in a few minutes; the print is then washed and dried. The gelatine surface is now sensitised with a ferro-prussiate mixture, and an image in Prussian blue obtained through the second negative. What novelty the process possesses lies in the use of the rubber coat for isolating the second film from the first, but that it is a device which has been used in three-colour printing regularly in past years.

### Herr Worel on Dr. Smith's Colour P.O.P.

Several of the German papers publish an article by Herr Karl Worel, of Gras, relating his experience of the bleach-out paper shown by Dr. Smith before the Royal Photographic Society a month or

tory work. As Dr. Lowe points out, the chief merit of the pocket spectroscope is not that it can be carried in the pocket, but that it can be applied to any surface or solution and the whole spectrum observed. With a view of holding test tubes and similar

two ago, and now manufactured by him under the name "Uto." Herr Worel, as one of the earlier experimenters in the bleach-out method of colour printing, has a right to be heard. He writes: "Uto" paper has a reddish-black colour, which arises from two superimposed films, a red next to the paper, and a bluish-green above it. The red film needs to be sensitised in an oxidising solution of hydrogen peroxide; the blue and yellow film is supplied in a sensitive state, the sensitiser, betrayed by its odour, being anæthol. This ethereal oil affects, though only to a slight degree, the red film, for when the paper is exposed to light under glass it bleaches out almost to white, whilst if unprotected during exposure the red persists, even after an hour. In the first case the escape of the

anæthol is delayed, in the second it is hastened by the heat.

"It would be advisable to sensitise the red film more strongly, or the dye will not permit of this, to use another which is highly sensitive to anæthol. It would then be possible to dispense with the hydrogen peroxide altogether.

"With fifteen minutes exposure at the most I obtained on 'Uto' paper in brilliant July sunshine copies of a transparency coloured oils, which were brilliant in all colours and gradations and true to the original. The prints are very simply fixed in immersion in benzene at 70 to 80 degrees."

Herr Worel's conclusion is that the new paper opens a new field in colour photography.

## COMMERCIAL PHOTOGRAPHY.

The work which a photographer is called upon to do in the photographing of articles of manufacture for catalogue and illustration often involves knowledge of methods which are only learnt by experience, and it may therefore be of advantage to those anxious to qualify themselves for this growing branch of business if we reprint an article from "Wilson's Magazine," in which Mr. Edward J. Davison writes of a few expedients found to be of value in practice.

### Photographing Bottles.

When photographing bottles and small articles, where it is desired to have a perfectly white ground, and where it is difficult to block out the background, an excellent way is to use a ground glass for the background and get the light through it from a window at the back. Where a window cannot be used, I arrange a mirror to reflect light upon the ground glass.

The uprights supporting the ground glass must be free and clear between and have nothing to obstruct the light coming through the ground glass. Sometimes a background of white cardboard can be lighted from above, but the other is such a simple plan that I would advise its use. Where the oval or round surfaces of the bottles act as mirrors and reflect the angle bars of the skylight, a screen of tracing cloth should be placed between the camera and the skylight to cut off these marks. This precaution is necessary in a great variety of work, in order to avoid harsh high lights and images reflected into the articles themselves if they are polished. Do not try to do away with every high light, however, for that would leave a flat-looking print.

### Chinaware Bric-a-Brac.

In making photographs of chinaware, bric-à-brac, and similar small articles for commercial purposes, it is necessary to preserve the design, form, and details of the originals. I know of nothing which will accomplish this so well as an arrangement of movable shelves lined and edged with black velvet, on which the articles are arranged so as to show their valuable points. The illumination should be secured by light coming through tracing cloth. This will kill reflections and soften or obliterate shadows.

Among the most difficult lines brought to the studio of the commercial worker, that requiring the largest amount of skill and patience is decorated china having a polished and oval surface. One must use an orthochromatic plate, of course, and sometimes a colour screen. About the only light that can be used is a side or top light, or both, coming through tracing cloth. This will diffuse the light and prevent a patch of high light often right in the decoration. A streak of high light on the edge and handle of a cup and saucer is an advantage. This style of lighting will show a roundness and softness not obtainable in any other manner. If one is not familiar with the correct position for such articles, it is best to consult some catalogue and find the standard method of presentation or display before attempting, and I would like to emphasise the necessity for sticking to standard positions with almost everything the commercial photographer gets in his shop. There is a right and wrong position for everything, and much time will be saved if the photographer finds out beforehand just what that is. For instance, a cup and saucer must show the back as well as front edge at the top, so that it must be tilted a little towards the camera, or the

camera look down on it and the swinging back used to keep the perpendicular lines rectilinear. A long-focus lens and long-bellow camera are necessary for this work.

### Silverware: Cut Glass.

Where much silver or glassware is to be handled a stand with movable shelves is a necessity, and the shelves should be held on pins so that they can be placed at different distances apart. For cut-glass the finest light is a strong top light. This will give brilliancy to the facets and liven up what would otherwise be dull. In some factories the pieces are dipped in whitening tinted a light grey before photographing. These shelves will do for silverware which should be photographed before receiving its polish; but this can seldom be done away from the factory. A good method for dulling bright spots is to rub the place with beeswax and then polish with the hand. This is a simple remedy, and can be done easily and quickly with a little practice.

When flat surfaces have inscriptions that do not show, it is a good plan to rub into the engraving a black powder which jewellers use in their work. It will usually stick sufficiently well not to need anything mixed with it. When prints are to be made from negatives of coloured subjects and the darker colours are too thin in the negative, those parts of the negative can be tinted with blue aniline, but it is very skilful work. The colour is, of course, applied on the glass side. This dodge is old to most portrait workers, and enters largely into the retouching of commercial negatives of solid articles, such as metal ornaments and the like.

### Legal Work.

This is a most unsatisfactory class of work, for several reasons. One never knows when he will be called upon to go into court to testify, nor how much time will be consumed, so it is difficult to fix on a price that will justify. I have made a great many negatives for this class of work. A correct record should be kept of each exposure, showing the position of the camera, the exact locality of the place, if outdoors, and the direction in which the lens was pointing. These details should be lettered in the negative, thus "Looking N.E. at S.W., corner Sixth and Locust Streets, K. C., Mo. Camera located fifty feet from lamp-post on S.W. corner (or, at S.W. corner). Taken on January 15, 1903, by ———." Do not make a print from any legal negative until such data is shown, so as not to burden your mind with remembering these circumstances; lawyers will usually accept such wording and waive a personal appearance in court. It is well not to remember anything except what the negatives show; it will save embarrassment in cross-questioning. Records of these exposures in legal work should be kept in a separate book for easy reference. Charge double the usual prices for this class of work as compared with ordinary negatives. If allowed witness fees, it usually takes more time to collect them than they are worth, so that it is unwise to figure on anything except the price of the negative and so many prints. One set of prints should have muslin back and top for insertion in the "pleadings."

### Copying Documents.

Another class of work requiring great skill is the photographing of indistinct and illegible documents. I recall a case of this sort

which took me several hundred miles from home, and the work consisted in photographing two pages of a letterpress copybook. The copies were in very faint blue typewriter ink, on a manilla-coloured paper. The work had to be done in the private chambers of the judge, before whom the case had come, and I had to make use of what could in the way of a copying rack. I bought a number of rubber bands and a sheet of white cardboard, and put the white card under the leaf, leaving the back of the impression outward, as the ink was fainter there than when it came through the paper. The rubber bands were used to hold the page flat and in contact with the cardboard. I set the book up by a window, used a colour screen and orthochromatic plates to hold the blue ink, and made my exposures. These gave me reversed negatives, of course. When I arrived home 18 x 22 bromide enlargements made from the glass side of the original negative, gave me a correct transcript in the print. With this bromide, the negative set in a window and a strong reading glass I deciphered each letter, and, as I was certain of it, traced it in its proper place on the enlargement. In two or three days' time I had the document correctly figured out, so that it could be plainly read. This is expert work, and should command a high price.

#### Furniture.

I have done so much work in this specialty and have become so accustomed to working in all kinds of light that wherever possible I prefer to work at the factory. If I have several windows to work by, I put tissue paper over them and work with the light directly behind me. The walls and ceiling should be white. Work well back into the room and the light will be more even. Use orthochromatic plates and give full exposures, even to the point of over-timing. The lens for this work should not be less than 14 inches

focus for plates 8 x 10. The camera should be fixed to look downward on the furniture, so as to give the back edge of seats and couches. Furniture is usually photographed in the "rough," or before it is polished. Generally the firm will have a catalogue to guide you in size and position.

If one is careful in placing the background and works well away from windows, properly prepared, he will seldom have to do any blocking out. Where this is necessary the opaque made by Alvord is extremely useful. It is fine-grained, very soluble, and can be used in a pen for writing on glass or paper and for lettering on the film side of a negative. Use a small butter plate, into which put some of the opaque from the pot, adding water enough to thin it as thin as it will cover. This opaque dries quickly, and will never "pull" when going over it a second time. Where fine angles and small parts have to be blocked out a fine-pointed soft steel pen can be used perfectly, putting the opaque on the pen with the brush. If you are working on films and wish to number them, you can do so on the celluloid side, and this is an advantage where one is not an adept at lettering backwards. One way is as easy to me as another. Never use India ink in blotting out, as it will crack when it is dry. It is not necessary to block out the entire negative, as yellow or red cover paper can be cut out and pasted on the negative to cover the parts left from the opaquing. Some photographers make an untuned print carefully cut round the object and fit this on the negative, but it does not equal the other method. To keep your negative from spreading on the negative and getting on the figure, use a lead pencil, going around the subject; this gives a surface which will repel the opaque. Straight lines can be done with pen and a ruler.

## FREE ENLARGEMENT FRAUDS.

ONE of the cleverest skits of the free portrait business as worked by Tanqueray and his imitators appeared some year or two ago in "Judy," in whose columns the foibles and follies of the day have constantly come in for good-natured ridicule. This lampoon The Professional Photographers' Association have reprinted from the pages of "Judy" as a separate sheet, and the reprint is one which we hope every one of their members will keep in his possession, for in the event of his town being invaded by the free portrait canvassing swindlers no better object for the shop window could be found. Photographers have reason to be grateful to "Judy" for its humorous skit, the text and illustration of which we are taking the liberty of reproducing.

### THE ROTTENOTINT PORTRAIT

Is the Most Marvellous Offer Ever Offered.

A SIX-SHILLING PORTRAIT FOR EIGHT AND THREE HALFPENCE.

SEND ALL AT ONCE.

To readers of "Judy."—The Editor is still completing arrangements whereby readers can obtain

A LARGE FULL-SIZE ROTTENOTINT PORTRAIT,

superbly packed in pale blue paper, and secured with pink twine, for the small sum of Eight Shillings and Three-halfpence Post Free on receipt of Six Shillings and Sixpence.

HOW TO OBTAIN THE WONDERFUL PORTRAIT.

All you have to do is to send all at once Nine Shillings and Ninepence, together with your Dog Licence and Birth Certificate. We do the rest. In sending, please state whether for hot or cold climate.

THE FRAME ALONE

is worth One and Fourpence (27ft. by 31ft.), with full directions how to use it. Testimonials from all the leading Physicians in Drury Lane. Write your name and address plainly in ink (red preferred) and send us Eleven Shillings and Three-Halfpence to cover postage. If, after reading this, you fail to understand the price, send us another Shilling and Sixpence. The portrait will not be sent unless desired.

The Rottenotint is a silent process known only to the Artist.

"Truth" has given me notices for years.  
Two portraits for Three Shillings and One Halfpenny.  
Specimens can be seen at the Offices on payment of Seven Shillings and Sevenpence.  
The "Morning Leader" says: 'Oh, rot!'  
Agents wanted Five Minutes after Portraits are received.

SAMPLE OF WORK.

Mr. Tanqueray, the well-known Inventor.

A FEW TESTIMONIALS.

Dear Judy,—Rottenotint to hand this morning. The frame still

works a little stiffly, but that, no doubt, is a fault which time alone will rectify. The portrait itself is marvellous. Who is it?—O. O.

Dear Judy,—The Rottenotint has not yet arrived, but I gather that it will be here now shortly. The engine has been repaired, and no further breaks-down on the line are anticipated. In order to avoid delay this end, I have arranged to have it conveyed from the railway in a closed van.—Yours hopefully, Smith.

Dear Judy,—I have your Rottenotint of the 21st inst., for which please accept my heartfelt thanks! Will you please say whether it

should be boiled in hot or cold water? I have looked it up Nuttall's, but can find no reference to it.—Yours truly, A. S. S.

Dear Judy,—My wife and I have now returned after the long voyage recommended by medical experts, and are, therefore, prepared to receive Rottenotint. Wire as soon as dispatched. I hope for the best.—Yours confidently, Thos. Jay.

Dear Judy,—Rottenotint almost arrived. We can hear it at the of the street. Many, many thanks! Thanks! Awfully obliged. Delighted, in fact! Thanks!—Flo.

## PHYSICAL CHARACTERISTICS OF RELIEF ENGRAVINGS, ESPECIALLY RELATING TO HALF-TONES.

From "The Inland Printer."

In the course of these researches\* it has been found that the work has been extended and made more laborious than ordinarily necessary, because there were no tables giving data as to screen pitches, unit areas, diagonal pitches, dot diameters, dot areas, white and black dots relation to unit area, etc., available.

Out of these disadvantages have grown Tables G and H. These will enable anyone to make various comparisons without having recourse to many detailed calculations, and in some instances without making any whatever. They are arranged to save the time of the busy worker who turns out large quantities of work per day and who is deserving of far more recognition than is usually accorded him.

When one considers the minutiae of the various dimensions that he almost unconsciously deals in, the degree of perfection attained is almost marvellous. It is thought, however, that the process-man

Fig. 16.—Showing change in size and depths of 110-line engravings, Figs 9, 10, and 11, tabulated in Table F and shown in Fig. 17.

will find the tables more serviceable if some explanation is given as to the origin of the various values, as well as a concise definition of what they mean. In Table G are given the following values for various lines per inch:—

**Lines per Lineal Unit** (No. 1 of Fig. 18).—This has to do wholly with the number of lines found on the screen or the engraving within any given standard dimension. Among English-speaking peoples, the number of separate lines in each inch is used. The other unit is the centimetre of the metric system of measures. (There are 2.54cm. in lin. and .3937in. in each centimetre.) The lines per lineal unit, as ordinarily used, are expressed as lines per inch, and they consist of the numbers given in Table G. The principal standard screen numbers are listed. Of course, special rulings are frequently made, and it should be stated that these researches and the tables, diagrams, and illustrations used are all

\* The previous articles from "The Inland Printer" have appeared in the B.J.P. for April 27, June 8, and June 29.

Note.—No. 11: White dot clear spaces are the same as the dot diameters.

Fig. 18.—Illustrated Glossary of Half-tone Engraving Terms.

based on screens in which the two sets of lines are displaced 45 deg.; other angled screens require special investigations. If there is any question as to the lines per inch of any half-tone print, they can be easily counted by simply placing a rule over it and, with the aid of an eye-glass, counting the lines in a quarter of an inch, which, multiplied by four, will give the number per inch. The basis of comparison be  $\frac{1}{16}$  in. or 1-10 in., the number should be multiplied by 8 or 10. A very convenient half-tone screen indicator is published by the Suffolk Engraving and Electrotyping Company, of Boston.

SCREEN PITCH (No. 2 of Fig. 18).—The distance from the centre of one line to the centre of an adjacent one is known as screen pitch. It is expressed as a fraction of the unit, either an inch or centimetre. It is the shortest distance between the centres of any contiguous dots. At sixty-five lines per inch the value would be .001538 in., approximately 1-256 cm. In the tables the value is expressed in decimal parts of an inch, as .01538, which is the equivalent of .001538 in. This value is found by dividing 1 by the lines per inch,

“whites,” as the white dots (o) of the shadows will ordinarily take care of themselves. The depth in the shadows cannot be accentuated beyond that interrelation which recognises the depths of the various portions of an engraving as being about proportional to the intensity of the light reflected from the corresponding portion of the subject.

UNIT AREA (No. 5 of Fig. 18).—One of the most important factors in determining the tonal relations of an engraving is that of the interrelated areas of dot faces. This decides largely how much “colour” is present in the different parts of a plate, and on it depends the quality of brilliancy, when the relation of dot area to unit area is considered. Without comparing the relation of dot areas to some unit, they are meaningless and of little value. Unit area is not the same for all lines, and it is found by squaring the screen pitch, or, in other words, by multiplying the screen pitch by itself. Unit area may also be defined as the area of a unit square (No. 4 of Fig. 18) whose sides are equal to the screen pitch, and when one side is multiplied by the other one will give

Fig. 17.—Showing change in size of 110-line dots of Figs. 9, 10, and 11, and Table F, and Fig. 16.

which, in technical language, means that the decimal equivalent of such a fraction is the reciprocal of the number of lines per inch. It is necessary to know this in order to calculate unit area, and therefrom to determine the percentage value of black or white of any given size of dot.

DIAGONAL PITCH (No. 3 of Fig. 18).—This dimension is the distance from the centre of one dot to the centre of another in a diagonal direction. It may also be said to be the greatest distance between the centres of any two contiguous dots. It is found by squaring the screen pitch and taking two times this amount and extracting its square root. In short, it is  $\sqrt{p^2+p^2}$ , wherein the letter p stands for screen pitch. It is useful when one desires to establish the printing quality of the black dots (●) in the “whites.” In the instance of a 65-line screen, the diagonal pitch becomes

$$\sqrt{\frac{1^2}{65^2} + \frac{1^2}{65^2}} \text{ or } \sqrt{.01538^2 + .01538^2} = \sqrt{.000473} = .02175.$$

The printing quality may be considered as applying only to the

the area. Assuming 65 lines per inch, one multiplies 1-65 in. by itself and finds the product (.01538 × .01538) to be .0002365 square inch. (In the metric system unit area would be  $\frac{1}{25.6}$  cm. ×  $\frac{1}{25.6}$ , or .039 × .039, which gives .00152 square centimetres.) The unit of measurement for the areas is taken as the 1-10,000,000th of a square inch. This is done because the carrying along of the ciphers becomes an unwieldy process, and instead of using .0002365, it is less complex to only use the integers and let 2,365 represent unit area at 65 lines per inch. Since the dot areas are also given in terms of the same unit, they may be compared at once.

“COVERING” DOT.—This term is an improvised one that indicates the theoretical diameter to which the white dot (o) of the shadows would have to be increased to an imaginary size so that four dots would meet at the centre of a unit square (shown at 6 of Fig. 18), and thereby entirely cover a unit square. The diameter of such a “covering” dot will be the same as the diagonal pitch.

The highest percentage values given in Table H indicate the

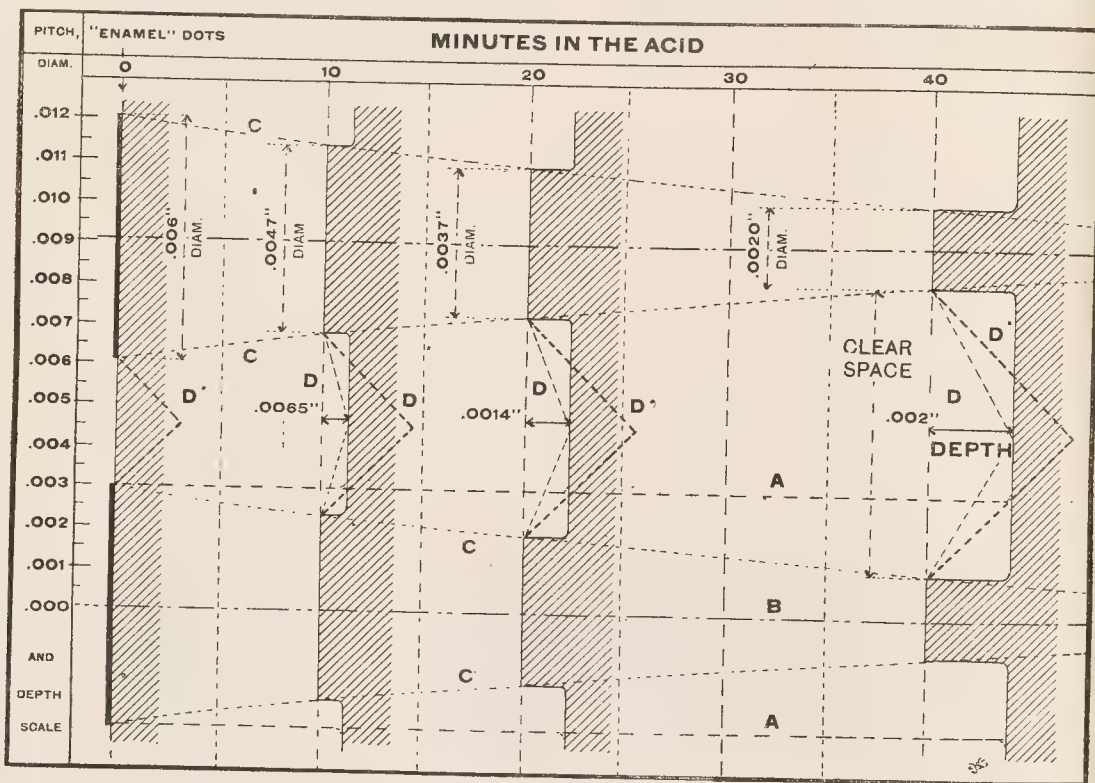

portion of the combined area of four covering dots that falls within the boundary lines of a unit square. Since a part of the area of each "covering" dot falls over a similar part of another dot, these portions are said to overlap, and the amount of the overlapping within a unit square is the excess beyond 100, of the highest percentage values given in Table H.

In Table H, which is combined with Table G, are given the following values for various diameters of dots and different screens, which are arbitrarily selected:—

**DOT DIAMETER** (7 of Fig. 18).—This refers to the diameters of dots, whether white or black, and it is approximately found from inspection of Fig. 7 for 65, 110, and 150 lines per inch at any assumed time in the acid, or by direct examination with a microscope that has a screen reading at least to .002in., from which it

**DOT AREA** (No. 8 of Fig. 18).—This represents the actual printing surface, and it is found by squaring the dot diameter and multiplying by .7854; briefly,  $d^2 \times .7854$ , in which  $d$  represents the diameter. Dot areas of from 5 to 15 are so small as to be practically indiscernible to the naked eye of even an expert. When they represent black dots in the "whites," their presence in a print well made, is only indicated by a slight overcasting shade, which to the uninitiated, would appear like "nothing at all." A diameter of .0025in. has an area of 49—what? It is a long way around to say 49 ten-millionths of a square inch. Why not 49 talbots, and honour the memory of Fox Talbot, the celebrated Englishman, who did such pioneer work in the production of printing plates from photographs? He was born in 1800 and died 1877. A talbot would represent the unit of area.

Calculated Characteristics.

Fig. 19.—Showing conventional form of dots, depth, diameter, and side action of 110-line engraving, Fig. 2. Tabulated in Tables A and B. The clear spaces are not diagonal, consequently the relation of depth to clear space is greater than if the diagonal distance was used.

is not difficult to estimate to .001in. and to half-thousandths of an inch.\* Direct examination guards against the modifying effect of a considerable variation in specific gravity and temperature of the acid. In Table H the dot diameters are given in thousandths and half-thousandths, which are sufficiently close for practical work, as inspection of the changes in percentages for half-thousandth variations in diameters will show. For the finest screens the variation should be in quarter-thousandths. If one has a certain area and wishes to know what dot diameter will be its equivalent, it is only required to divide the area by .7854 and extract the square root of the quotient. From the column of dot areas in Table H one can approximate the dot diameter for a given area by selecting the area that comes the nearest to the one in question and noting the corresponding diameter.

\* Screens of .001 inch are easily procured.

**PERCENTAGE RELATION** (Nos. 9 and 12 of Fig. 18).—This is the proportion that dot area bears to unit area. It is always a fractional part of the whole, and is found by taking the dot area as the numerator and the unit area as the denominator of a fraction. The decimal equivalent of such a fraction is the value given. If the dot in question is a white one (○), the percentage value will be in white; if a black dot (●), it will be in black. The difference between the given percentage and 100 will always give the converse. Suppose a .0025in. diameter black dot (●), at 60 lines; this shows a percentage of 2.07 of black, if a black dot is in question, and under this condition the white would be represented by 100, minus 2.07 or 97.93 per cent. Should a white dot (○) be under comparison, the names "black" and "white" would be transposed.

These percentages are given in Table H for 50, 65, 85, 100, 110, 150, and 200 lines per inch, and one can approximate therefrom the probable values for other lines per inch.

**CLEAR SPACE** (Nos. 10 and 11 of Fig. 18).—The space from which the material has been removed between the edges of any two adjacent printing surfaces is called a "clear space." It is used, in determining the printing quality of relief engravings, in conjunction with the depth to which the material has been removed. For the "whites" it is found by subtracting the dot diameter from the diagonal pitch. This is given in the table for the same screens as the percentages. In the case of a 65-line screen and a .002in. diameter dot, the clear space is .01975in. If this is divided by the depth, and the quotient is taken as the denominator, and 1 as the numerator of a fraction, and the fraction is then expressed decimally, a value indicative of the printing quality will be found. If one would care, as a matter of academic interest, to ascertain this for the white dots of the shadows, one would consider the clear space as identical to the dot diameter, and proceed as above. Table I. gives the printing quality for various depths and clear spaces.

**ETCHING DEPTH** (No. 13 of Fig. 18).—This is not given in the table, but the theoretical depth based on the side action in flat etching is approximately one-half of the reduction in diameter of a given dot that has taken place subsequent to a previous observation. Suppose at an examination a certain set of ● dots measured .006in. in diameter on the "enamel," and at another examination they were .004in. smaller, leaving them but .002in. diameter: theoretically the depth would be one-half of the whole reduction, or .002in. For the black dots this theoretical depth is so small, as shown in Fig. 16, but for the smallest ○ dots it is approximately accurate. These deductions are based on depth measurements of Figs. 9, 10, and 11, given in Table F. They are also shown in "Pictorial" graphic curves of Fig. 16, wherein different conditions of time of etching, dot diameters, dot areas, calculated and measured depths are illustrated; and in Fig. 17 the same data are presented in four-dot sets, numbered from 1 to 2 (inclusive), similar to Fig. 16, showing their relation to unit area.

Fig. 18 is an illustrated glossary of the various terms used in the course of these articles, showing eighteen small figures, which it is thought will materially assist the reader.

Fig. 19 shows the calculated relation of depth to "clear space" of the data of Table A. The clear space is not in a diagonal direction.

(To be continued.)

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between August 20 and 25.

**CAMERAS.**—No. 18,690. Improvements relating to photographic cameras. Reginald Herbert Payne, 111, Hatton Garden, London, E.C.

**COLOUR PHOTOGRAPHY.**—No. 18,741. Improvements in colour photography. Albert Davies, 24, Southampton Buildings, London, E.C.

**DARK SLIDES.**—No. 18,756. Improvements in the construction and manipulation of dark slides. John Martin Jones, 14, Mellor Road, Prenton, Birkenhead.

**CINEMATOPHGRAPHS.**—No. 18,962. Improvements in cinematograph projectors, cameras, and like machines. William Cecil Jeapes, and Percy Henry Bastie, Greenland Place, Camden Town, London, N. W.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**COLOUR PHOTOGRAPHY.**—No. 16,104, 1905. The invention has for its object to provide improved means for producing pictures in colours. All the colours are obtained from a single ordinary

or original negative. A colour screen or filter is interposed between the colour-sensitive plate or film in the camera and the object to be reproduced in colours. No special colour-sensitive plates or screens are required; any colour-sensitive plates procurable in the market at the present moment are suitable. In order to obtain first-class results the original negative must be fully exposed and developed to a good density, the densities (representing colour in monochrome) should preferably be as nearly as possible as follows:—White in the original scenes should be opaque in negative, blue in the original scenes should be semi-opaque in negative, green in the original scenes should be middle density in negative, yellow in the original scenes should be middle density in negative, red in the original scenes should be faint density in negative, black in the original scenes should be clear glass in negative. The scale of colour in the monochrome negative can be obtained in any desired ratio or intensity according to the requirements of the operator. For instance—supposing the commercial Lumière "B" plates are being used, and the scale of colour in the monochrome negative is required as above stated, the operator in this case would employ a deep yellow or light orange red screen interposed between the colour-sensitive plate or film in the camera and the object to be reproduced in colours, so that the image formed by the lens on the colour-sensitive plate is screened with the required colour during exposure, and if the exposure has been fairly correct, then in developing the plate (in the ordinary manner) it will be seen that the colour screen has cut down the blue rays of the spectrum, making the density representing the "blues" in the monochrome negative not so dense as the parts of the monochrome negative representing the whites. The same will be noticed in the greens and yellows, they being of density different from the blues. The reds will only have a faint action on the colour-sensitive film, and will be therefore of faint density, next to black which has no density. We shall now have a negative as required. On the other hand, supposing the scale of colour in monochrome negative is required to be reversed, i.e., white; opaque, blue, faintest density; green, middle density; yellow, middle density; red, strongest density next to white; black, clear glass. A fresh Lumière "B" colour-sensitive plate would be employed, but in this case a different colour screen must be used, namely, a strong red, but not sufficient to stop out all the blue rays of the spectrum. In developing this plate the whites will be opaque; blues, faintest density (through the red screen cutting off as much as desired off the blue rays of the spectrum); yellows and greens, middle density; reds, strongest density (next to whites), the red screen in this case accentuating the reds on the colour-sensitive plate. In this manner by using different colour screens for the result aimed at any desired scale of colour in monochrome in the negative can be accomplished. The results can be modified by using different brands of plates. The densities of the negative play an important part, but practically any clear good negative can be printed from. If the scale of gradation in the negative is altered (presuming that blue is the faintest density in this case) then the positive must be printed accordingly. Presuming the existence of such a negative or one as near as possible as first described above, a red positive is first made by any known colour process printed from the negative, taking care that only the clear portions of the negative (representing black) and the most faint density (representing the reds) only are printed. This red positive (from the second operation) is registered in close contact with the same negative and a fresh positive is printed again in yellow, or green (by any known colour process) on another surface until the middle density only is printed. A red positive is made first and then superimposed on the same negative before printing the next colour (yellow or green), because the red positive is required to act as a light shield, so that it will block out the red density in the negative and prevent it from printing again on the next colour, unless the colours happen to blend, when of course the gradation and density of the negative will step in and give the required impure or mixed colour or colours. We now have a red and yellow (or green) positive, each picking out its own colour and

mixture of colours. We have simply to superimpose the red and yellow (or green) positives on each other and place them in register with the same negative and print the next density (blue) by any known colour process in blue, the red and yellow (or green positive) serving as light shields to prevent other densities from printing in the wrong colour. We shall have now three positives in red, blue and yellow (or green) respectively, each positive picking out its own colour according to the density of the negative, and to make a picture from the negative as true as possible in colour to the original scene. We print (without any positive shield, or shields) a light monochrome positive in black from the same negative (to give black in clear portion of negative), and when we superimpose and register the red, yellow (or green) and blue positives (or in any suitable order or degree of colour) on the monochrome positive the picture will be a complete triad of colour, the monochrome print giving the black, and the red, blue and yellow (or green) positive, giving all the other colours and mixture of colours when registered and superimposed on each other. As an alternative method instead of printing the positive light shield or light shields in colour by any of the known colour processes they may be made in monochrome from the one negative on a thin transparent material, the same being superimposed and registered in contact with the negative when printing the colour positives as already described; or negatives can be printed from the light shield (or shields), and used as in two, three, or multi-colour work. For instance, the light shields may be printed on very thin celluloid films coated with a suitable bromide or chloro-bromide emulsion. These films are then printed as described, and are developed like a lantern slide positive in monochrome, and when fixed, washed, and dried, are employed in the same way as the coloured light shields to obtain the minus colours from the one negative. As a guide for printing the light shields to the correct opacity in the one negative, it is well to place a colour chart (or such like) if red, blue and yellow, so as to be included on the edge of the original negative when exposing the negative in the camera. By printing or washing out the colour, or developing the positive light shields to the visual opacity, more certain and perfect colour rendering can be obtained from the one negative. Or instead of a colour chart being placed by the side of the object to be photographed we can place a small colour chart of transparent colours, and suitably graded on transparent material within the edge of a dark slide in a suitable position so that they are exposed during the time of exposure, and act in a similar manner to a colour chart. When it is desired to produce several coloured pictures or images, as above, each of the positives above mentioned is used as a negative from which is printed a monochrome negative. These monochrome negatives having been developed and treated in the usual manner are used for printing any desired number of corresponding positives which are dyed or inked with the requisite colours by any known colour process, and are subsequently used for superposition to form coloured pictures or images as above set forth. In some cases the colour effect may be obtained by superposing one or more positives printed in colour, and one or more negatives also printed in different colours for animated pictures or otherwise. In some cases, having obtained two negatives in monochrome from the same negative, a positive of intermediate density may be obtained, or a negative of intermediate density may be printed through a positive, and a negative obtained from the original negative and superimposed. For producing animated pictures in colours a series of negatives (at equi-distance as near as possible) is made on a colour-sensitive surface and through a suitable colour screen. The films for use in cinematographic reproduction in colour are prepared by first producing the usual series of negatives on a sensitive surface (preferably on a colour-sensitive film, and through a suitable colour screen), and then by successive printing and masking in the manner described, producing from the single set of negatives one or more sets of positives or negatives either side by side on one film or on separate films, each corresponding to some particular gradation or range of gradation in the original set of negatives, the projection in colour on the screen from the sets of coloured positives taking place by any known colour process. Or a revolving

prism may be used to present two or more images on the exhibiting screen at the same time in different colours and superimposed, or we may transmit coloured rays from the back of the film plate to act as colour sources instead of the usual screens front, between or behind the lens or lenses. Films for animated pictures may also be printed from blocks or light shields, positive film containing the colour positive being exhibited the screen in the usual manner. For producing photo-mechanical blocks from one negative the process is as follows:—A colour image is made by superimposing colour positives on a black or white or a monochrome print in colour as above described, and the colour picture then photographed again in the usual manner through colour screens, and from the resulting negatives, blocks are made in the usual manner. Or light shields may be turned into and used as printing blocks, or a block or blocks from the original negative can be set up in the printing machinery in usual practice, and the light shields caused to come in contact with the block or blocks at certain parts, the colour inks alternating in different colours. The light shields when used as blocks are minus colours through being printed in the first instance to certain densities of the original negative, and as is well known to photographers, the minus colours in a block are depressed (do not absorb or take up much or any colour ink), whilst the major colours in the same block are raised (relief) and take up the ink only in these parts or vice versa; will therefore be very easily seen that through only printing certain densities from an original negative, we are creating the assistance of light shields, minus colours from the one original negative, and therefore each light shield in itself will be minus colour to its fellow, and can be used in the usual way for block making and printing in multi-colours. Instead of colour inks, the blocks may be printed from by electricity under Patent No. 27243 of 1897 granted to W. Friese Greene. For advertisements, posters, etc., the negative can be retouched if necessary by hand in certain parts to accentuate or leave out unrequired colours (density and gradation in the negative or light shields from which negative any number of negatives can be made in various colours for mechanical or other printing. W. N. Lascelles Davidson, 20, Middle Street, Brighton.

**STEREOSCOPES.**—No. 25,591, 1905. The invention consists of a reflecting stereoscope of the kind in which whilst one view is observed directly the other is seen by reflection in a mirror of which the plane is approximately equally inclined to each of the two picture plates, consisting of two panels forming a dihedral angle, and between which is arranged a frame or table placed in the plane of the bisector of the said angle and bearing on one side of its upper part a mirror or a totally reflecting prism, one of the panels of the angle, that which faces the back of the mirror, carrying the erect stereoscopic view, while the other panel, opposite the reflecting surface of the mirror, bears the reversed view; the reversed view may be arranged either top to top with the erect view, or with the horizon lines on the

FIG. 1.

FIG. 2.

same level, and both cut the hinge of the angle perpendicularly at the same point. The arrangement shown in Fig. 1 supposes that the two stereoscopic pictures are looked at in which the two lines of the horizon are both perpendicular to the hinge and intersect the hinge at the same point. The first picture is placed in its ordinary direction as shown by the letters L P on the plane A to the right of the dihedral angle for instance; the picture can be regarded directly by the right eye repre-

sented in the diagram by a dot. The other stereoscopic picture, that is to say the reversed left picture is placed on the left panel B of the angle, the corresponding points of the two pictures being aligned to perpendiculars drawn to the hinge of the dihedral at the same point of the said hinge. In the bisecting plane C is placed, on the left face of the same and on the upper part, a mirror  $\alpha$  in which the observer can see by reflection, by means of the left eye, represented by a cross, the reversed left stereoscopic picture. The reversed picture is again reversed by the mirror, and its actual image thus combines with the right picture L.P. seen by the right eye in the plane A. In the arrangement adopted in Fig. 2 the stereoscopic pictures are arranged top to top. In this case the observer will not have his two eyes one at one side and the other at the other at the other of the bisecting piece C, but both at the same side of the said bisecting piece as indicated by the dot and the cross, and in such a manner that the left eye can easily see the reversed picture by reflection, while the right eye bears directly on the picture the right way up. In this theoretical figure in which the bisecting mirror has been given a great expanse for the sake of clearly defining its position there is supposed to be in front of the right eye an opening  $b$  giving passage to the rays of light to this eye. Leon Pigeon, Rue Millot et Dijon (Cote d'Or), France.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—

PORTABLE APPARATUS.—No. 18,345. Apparatus for travelling photographers. Schmidt.

## Exhibitions.

### C. F. INSTON'S PHOTOGRAPHS IN LIVERPOOL.

MR. C. F. INSTON, F.R.P.S., is giving the seventh of the series of "one-man" shows held this summer at the rooms of the Liverpool Amateur Photographic Association. It was he who started these shows, chiefly with a view to stimulating interest in pictorial photography in Liverpool, and the great success attained has fully justified the effort which has been made. In the present show 104 frames are hung, the majority being 12 x 10 and 15 x 12 bromide enlargements, framed in the passe-par-tout style. These are the backbone of the collection, all are hand camera work, and the variety of subjects, street scenes, dock scenes, landscape, river studies, figure studies, etc., show that all comes alike to Inston. He has "an eye for a picture," and, what is more, when he has got it he knows well how to enlarge, mount, and frame it, so that the whole thing becomes complete and satisfying. When Alvin Langdon Coburn took Liverpool dock scenes on purpose for his one-man show in April, he was supposed to have seen the last pictorial effect to be obtained on such subjects. Liverpool may now breathe again. Inston has shown that there are still "dock scenes" left, and No. 20, "The Black Sail," and No. 42, "The Barge," are fine examples of the class of work which can be found in abundance, if one knows how to see it, the latter being a by no means unimportant item. Many old prize-winners are to be found on the walls, the well-known "Whence and Whither," and "The Storm Rising," two of the author's most important works, being by no means the least pleasing.

In addition to the larger work, there is a series of some thirty half-plate platinotypes of very fine quality and tone. All these are developed with Inston's own formula, and are a very interesting part of the show.

Some eighteen frames, figure studies in the byways and back streets of Liverpool, demonstrate in a most striking manner the simplicity of picture making with such subjects, and Inston's special genius for arrangement, lighting, and "moment of exposure" is nowhere better seen than amongst these; they are well worth the

careful study of those interested in this line of pictorial photography. There are a few, some twenty or so, which are stand camera work. These are chiefly portraits; all the remainder are snap-shots, with a hand camera, and when one sees the variety of subjects so successfully rendered one must wonder why a stand camera is ever used, except for architecture and portraiture.

Inston is not only to be congratulated on the very high pictorial and technical excellence of his own show, but also on the effect his secretaryship has had on the work of the Liverpool Society, which latter has advanced by leaps and bounds during the past year.

C. THURSTAN HOLLAND, F.R.P.S.

### ROYAL CORNWALL POLYTECHNIC SOCIETY.

The seventieth exhibition of the Royal Cornwall Polytechnic Society was opened at Falmouth on Tuesday, September 4. Several divisions of the exhibition show a distinct falling off in the number of the entries, while others show an increase. Unfortunately the photographs are fewer in number than at the last exhibition, but the average quality is much higher. There is a large proportion of bold and striking work, and the general impression is that of a good and instructive collection of photographs.

The portrait and figure section is very strong. There are nearly forty entries, and not more than two or three pictures that can be adversely criticised. Although a moderate proportion of the portraits are professional work there is very little of the conventional studio portraiture, with its artificial accessories and posing. Nearly all the work is thoroughly good, showing character and strength in style, posing and execution. There is a fine series of portraits, mostly large heads, by W. H. Lanyon, of St. Ives, bold and striking in style; a series of portraits, more conventional work, though very good of its kind, by J. Lukey, of Camborne; and two strong portraits by H. T. Jessop, of Exmouth. The most notable figure studies are "The Evangelist," by L. C. F. Robson, and the well-known "Simple Simon" of Louis Dick. Mr. Robson's picture shows a group standing round an open-air preacher; it is raining, and the hazy atmosphere softening everything beyond the group, the reflections in the wet foreground, and the natural and pleasing arrangement of the group round the principal figure form a most pleasing picture. Miss Gertrude Boyns has two novel prints, one showing an artist finishing a picture for the Academy, the second, the reception of the rejection notice.

Landscape work is not nearly so strong as portraiture, though the entries are more numerous. There is very little work that is actually poor in quality, but, equally, there is little that is striking or really strong. Several pictures are strong in conception, but weak in execution. There is a fine study of a breaking wave by W. H. Lanyon. It is a strong carbon print showing an enormous wave just breaking on a rocky beach. The sense of movement is admirably conveyed, the spray surrounding the moving mass of water adding to the vividness of the impression conveyed. There is fine atmosphere and quality in Mr. E. Jarvis's "October Morn," but the print is scarcely sufficiently strong for its size; in the well-lighted exhibition room it looks weak.

In the architectural and other sections the entries are few, but most of the pictures are of good quality. The Rev. E. T. Clark shows a new and effective rendering of the stairway at Wells Cathedral, and Mr. J. C. Burrow two striking pictures of miners at work in coal seams.

The principal trade exhibits consist of Kodak cameras, etc., Goerz-Anschütz focal-plane cameras, and Johnson and Sons' photographic chemicals.

The judges, Dr. J. Clark, M.A., D.Sc., Messrs. Robert Fox, and Henry W. Bennett, F.R.P.S., made the following awards:—Landscape: First silver medal, Study of a Wave, W. H. Lanyon; second bronze medal, An October Morn, E. J. Jarvis. Portraits and figure studies: First silver medal, portrait, W. H. Lanyon, first bronze medal, portrait, H. J. Jessop, first bronze medal, Simple Simon, L. Dick. Architecture: First bronze medal, A Flight of Steps, Rev. E. T. Clark. Still Life, etc.: No award. Technical photographs: Second silver medal, Miners at Work, J. C. Burrow; second bronze medal, A Flash of Lightning, Sergeant Cleaves. Apparatus: Second bronze medal, chemicals and cameras, John Blaney.

## New Apparatus, &c.

The Ilford Exposure Meter. Sold by Ilford, Limited, Ilford, E. A new pattern of the Ilford meter, embodying recent patent protection, has now been placed on the market by the Ilford Co., and is an extremely complete guide to the exposure of the company's well-known brand of plates. It provides for the factors in exposure of plate speed, subject and diaphragm, and light, the latter being

calculated on the basis of Dr. Scott's well-known tables, in conjunction with a scale for weather conditions ranging from S (sunlight) to V.D. (very dull). Though the meter consists of four concentric dishes, the operations in calculating the exposure are but three in number:—

1. Set weather condition opposite plate.
2. Look out light figure in table of time of day and year.
3. Set subject opposite light figure.

The exposure for every diaphragm from  $f/4$  to  $f/64$  is then shown at once. The user can scarcely go wrong in this very simple procedure, since the three sets of scales are printed each in a different colour, and black must be set only to black, blue to blue, and red to red, when using the meter. This device is a great advantage in placing the meter in the hands of persons unacquainted with such forms of calculators, and should be sufficient to safeguard the meter perfectly from misuse. In such other respects, as compactness—the meter is but 2½ in. in diameter—and its ability to respond to the most varied photographic circumstances, the meter commands our warm approval. The price in card board is 1s.; in aluminium, 5s.; and the one instrument in conjunction with the additional light tables is ready for use in any part of the world.

**SOUTH ESSEX CAMERA CLUB.**—The third Continental excursion has proved an unqualified success, under the management of Mr. Walter D. Welford. The party numbered twenty in all, including friends from Skipton, Stockton, Rugby, Leicester, and Darlington. Something like 1,500 plates were exposed, one member using 120 in Bruges alone. This town was the success of the tour, the general saying being, "I should like a month there." Other places visited were Ostend, Blankenberghe, Knocke, Heist, L'Ecluse, Ghent, Brussels, Malines, Teuveuren, Namur, and Dinnat. Mr. Welford has been asked to arrange for another week in Bruges in September, which he will do if he can make up a party of eight or ten. Any of our readers desiring a week there should communicate with him at Alston Lodge, 61, Mansfield Road, Ilford.

**THE CANTON PRESS, LTD.**, of 15 Furnival Street, E.C., inform us they have amalgamated with the firm of F. Wetherman and Co., the well-known trade, colotype, chromo-litho, and art letterpress printers of Enfield, N., where they are erecting a unique plant consisting of Meihles, Centuries, Phoenix Platens, Aluminium Rotaries, litho, and colotype machines, for the production of art letterpress catalogues, three-colour work, and posters. They are also prepared to undertake chromo-litho for show cards, pictorial posters, etc., and colotype for pictures for fine art publishers, view books, book illustrations, picture postcards, art calendars, etc.

**HERR DUHRKOPF**, of Hamburg, was so pleased with the reception that his first collection of portrait studies met with in Bristol that he has sent sixty of his latest works to the exhibition which the Bristol Photographic Club is holding next month. Visitors to the exhibition may anticipate seeing a most interesting collection.

## New Materials.

"Scaloid" Tablets. Messrs. Johnson and Sons, 23, Cross Street, Finsbury, London, E.C., send us their booklet of photographic chemicals supplied under the name of "Scaloid." The booklet includes directions for the use of "Scaloid" developers (metol hydroquinone, pyro-soda, pyro-metol, hydro-quinone and amidol) reduce intensifiers and toning baths, and imparts much useful information on the use of these solutions. Messrs. Johnson also send samples of a new "Scaloid" toning bath for P.O.P., for which immunity from double toning and softening action on gelatine prints are claimed. The recent heat wave has provided us with excellent test conditions under which to examine the behaviour of P.O.P. the toning solution; the latter, we were pleased to find, was such to recommend the preparation in these respects.

### CATALOGUES AND TRADE NOTICES.

From Messrs. L. Gaumont and Co. we are in receipt of the current list of Elge cinematograph films.

Messrs. Gold Smith and Co. send us their catalogue of apparatus and accessories for midget photography, a comprehensive list of sixteen pages, which is sent free from 44, Chapel Street, Salford, Manchester.

The Ilford Company have just issued a booklet of the "Amateur plate, setting forth the characteristics of their self-developing plates. The booklet includes portions of a recent article by Mr. Snowdon Ward on the plate, and some illustrations of the plate's behaviour under difficult conditions.

Messrs. Wratten and Wainwright have good reason to issue a new price list, and to draw attention to it inasmuch as the period since the issue of the previous edition has been marked by the introduction of the new orthochromatic and panchromatic plates, and in addition, of the bathed pinacyanol and pinachrome plates. The new list very clearly specifies these various manufactures, and adds a number of useful notes on the selection of plates for the various purposes of orthochromatic work, three-colour photography, photo-engraving, and photo-spectroscopy. In all these branches of work, Messrs. Wratten have proved their ability to offer the photographer unusual facilities.

**An Incomplete Portrait.**—According to the "Evening News" last week judgment will shortly have to be pronounced by the Civil Chamber of the Cairo Mixed Court on a most amusing case. Some time ago a native barrister gave a commission to a Greek artist to paint his portrait in oils. It was a three-quarter face portrait and when the work was finished the native barrister was delighted with it, and invited all his friends to come and see the masterpiece. They did so, and to the advocate's disgust, instead of praising the work, maintained a polite but ominous silence as they gazed at the picture. Finally, one of them declared that the artist was clearly a fraud, as he had depicted his subject with only one ear! The advocate recognised that this criticism was only too true, and he rushed round to the artist's studio in a state of great indignation and declared that in view of the just criticism of his friends he would never pay for the portrait. The artist thought that the man of law was jesting, but when he discovered that the barrister was quite serious he was at pains to explain to him that in a three-quarter face portrait it was only possible for the person so depicted to have one ear visible. The barrister, however, declined to regard the argument as valid, and persists in refusing to pay, so the artist has been compelled to bring an action.

At Staines last week the premises of Arthur R. Lane, photographer and picture framer, were broken into. A French policeman named Taylor was found in the shop at 2 o'clock in the morning by a police-constable, and was charged with the theft of several small lens at the Feltham Petty Sessions. Prisoner was remanded for a week.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
.....	Bowes Pk. and Dis. Ph. Soc. ...	Outing to Grays and Low Street.
.....	Hull Photographic Society ....	Outing to Whitby.
.....	Aberdeen Photographic Assn.	Outing to Malden Craig.
.....	Hove Camera Club .....	Outing to Bramber.
.....	North Middlesex Photo. Soc. ....	Outing to Grays and Low Street.
.....	Manchester Amat. Photo. Soc. ....	Outing to Bollin Valley.
.....	Manchester Amat. Photo. Soc. ....	"One Man Show." S. L. Coulthurst.
.....	Southampton Camera Club .....	Print Competitions.
.....	Luton Camera Club .....	Lantern Evening.
.....	Hackney Photographic Society .....	"From Negative to Exhibition Print."
.....	Leeds Camera Club .....	H. W. Lane.
.....	North Middlesex Photo. Soc. ....	"The Scope of a Lens." W. W. Newbould.
.....	Aberdeen Photo. Art Club .....	"A Dive into Belgium." W. L. F. Wastell.
.....		Outing to Baughory House.

TORBAY CAMERA SOCIETY.—Members of this organisation are a band of steady workers, making definite progress and showing improvement in each successive album. In that for July, first place for pictorial quality and for technical excellence is due to "White Lilac," by Mrs. Marillier. This lady is a very capable worker in lower photography, and the present production is up to her usual standard, and altogether typical of her work. A figure study of two children, "On the Sands," while technically excellent, is rather poor in motive and arrangement. A very fine piece of work by Mr. A. J. Anderson, "After the Bath," has not secured notice, which is a pity. It is a study of contrasts—white diaphanous drapery against dark shadows, but very beautifully rendered, and of high quality. It is a little gem. His other contribution is a copy of Hemy's picture, "Seagulls," a most perfect bit of work. Captain Maxwell's "The Teign below Leigh Bridge," has great pictorial quality, and technique of the best. The choice of point of view is very good. He has also another meritorious scene on the same river. Mr. R. Morris submits two dainty productions, the better of which is "Polruan from Fowey," a quaint Cornish village, and "View from Hope Cove." Mr. G. Drury's "A Gathering Storm" is a fine sky study, and the scene, altogether pictorial, secured, apparently, in Torbay. Miss Marillier's floral "Study" suffers rather from a sense of flatness and want of care in arrangement. Her "Garden Scene" is very enjoyable. Mr. Carslake Winter Wood has a view of Dittisham, a place famous for its plums; the photograph in this case being taken at the season of blossoming. His "Sheepster," a Dartmoor village and church, is bolder and more satisfactory. Mr. A. R. Cox shows great promise in "Marguerites," and has a rather well-chosen scene in "Low Water, Putney." Mr. C. F. Rea has a fine eye for a picture, and sends two dissimilar ones—"Off the Fishing Grounds," an evening study, and "In Brixham Harbour," a rather good example of the rendering of water. Colonel Macmullen's portrait study of "Dorothy" is highly creditable. Mr. S. W. Garlands's little prints of scenes in Brussels are good in selection and technically excellent. The members of the society have not yet become contributors to exhibitions, but they might do so, possibly with credit to themselves.

ABERDEEN PHOTO ART CLUB.—The annual general meeting of the above club was held last week, Mr. G. L. Smith presiding. The various reports were read, and showed the club to be in a very satisfactory condition, financially and in membership. The following were appointed office-bearers for the year:—President, Mr. G. L. Smith; vice-presidents, Mr. J. Jarvis and Mr. W. R. Macgregor, M.A.; secretary, Mr. John Rae; assistant secretary, Mr. J. Dalgety; treasurer, Miss M. R. Smith; lanternist, Mr. J. D. Stephen; assistant, Mr. W. Cook; committee—Miss Dalgety, Miss Smith, Miss Robb, Miss Stephen, Mr. Stephen, Mr. Cook, Mr. McCulloch, and Mr. Kennedy. The winners in the monthly competitions were:—Prints—1, Mr. J. Rae; 2, Mr. J. Stephen; 3, Mr. McCulloch. Slides—1, Mr. W. Cook; 2, Mr. J. Rae.

A READER asks Mr. Fletcher, background artist, late of Bridgwater, to send his address to us in order that a commission may be put in hand.

Commercial & Legal Intelligence.

RIVAL PHOTOGRAPHERS.—At Richmond Police Court last week, James Waller, Chiswick, was summoned for assaulting and beating Lionel Hinton, of Hammersmith. Complainant said that defendant, who have been turned out of the Boathouse premises, came up to him and said that it was his fault that he had been ejected. Then he struck him on the nose. In reply to the defendant, he denied that he had threatened to bring a fighting man from Hounslow to deal with him. Samuel Brown said he heard defendant say to complainant that he would "pay him out," and saw him strike him in the face. He subsequently threatened witness also, saying, "I may as well be in for two." Defendant declared that it was a matter of trade rivalry. Last year he was touting for customers for Mr. Hinton's photographs; this year he was taking photographs on his own account. "Many a child," he said, "has been hurt worse at play than that old man was." Fined 20s. and costs.

A HADDINGTON PHOTOGRAPHER'S TROUBLES.—A petition for cession was presented at Haddington Sheriff Court last week at the instance of Joseph Thomson Gordon, photographer, Haddington. Petitioner stated that he used to carry on business in Dunbar. He came to Haddington in 1894, when he had about £100 of outstanding debts. He had been paying off his debts, but never was able to clear his feet and maintain himself at the same time. Two or three years previous to 1905 he found business worse than usual, and had a serious illness in his family. His profit per week in an average year was about 30s., while the household expenses went between 25s. and 30s. weekly. He had a wife and six of a family. A statement of affairs submitted showed liabilities £125 16s. 10d.; assets, £79 18s. 6d.; preferential debts, £14s 1s. 4d.; deficiency, £50 19s. 8d., this being, however, somewhat modified owing to the sale of several pieces of furniture. The petition was granted.

COMMERCIAL "INFANT."—To an action in the Stockport County Court, last week, brought by Coppock and Co., paint manufacturers, against Scholey and Teat, photographers, Doncaster, to recover £6 18s., the price of goods supplied, George Scholey, who said he was the defendant (Mr. Teat being imaginary), set up the plea of "infancy." Defendant produced his birth certificate. His Honour: I may say you are a very old-looking young man. I suppose you are the person mentioned in the certificate?—Yes. Why did you trade as Scholey and Teat?—To make a better show. His Honour pointed out that by itself the certificate was not proof, and that one of the parents must support the plea. It was an unfair way of doing business. He gave judgment against the firm other than Scholey, if he was an infant. It being stated that other actions were pending, and that there were thirty creditors, the defendant's solicitor suggested that the estate should be realised for their benefit. The judge thereupon adjourned the case.

THE affairs of Alfred Margand, photographic enlarger, trading as The Crown Art Co., 115, Seven Sisters Road, Holloway, N., came under review at the London Bankruptcy Court, on Tuesday, before Mr. Registrar Hope. The statement filed by the debtor disclosed gross liabilities amounting to £674 3s. 4d., to fully secured creditors £35, the value of the securities being returned at the same amount. The total liabilities expected to rank against the estate for dividend are returned at £637 3s. 4d.; assets nil. Replying to questions put by the Official Receiver, debtor stated that the receiving order was made on the debtor's own petition, and that he had been adjudicated bankrupt. He was of French nationality, and, after being in America for some years, he came to this country in 1901, and commenced business with a capital of £25 at 235, High Holborn, but he afterwards removed to 83, New Oxford Street, where he remained until October, 1903. He then went to Aberdeen and commenced a photographic enlarging business there in partnership with another person at 18, George Street. Some six months afterwards he retired, and received £20 for his interest in the business. He had since carried on business alone as a photographic enlarger, under the style of The Crown Art Co., at 118, Nethergate, Dundee, and he also used his private address at 115, Seven Sisters Road, N., for business purposes. He had also traded at Bridge Chambers, South Town,

Yarmouth, and at other provincial towns. Of the liabilities due to unsecured creditors, £500 was the estimated amount due to two agents or canvassers, who recovered judgment against him early in 1902 for damages and costs in actions for malicious prosecution. The whole of his stock and furniture at Seven Sisters Road were, in January last, sold under an execution levied at the suit of one of those creditors. He had also had judgment entered against him for £50 in another action for malicious prosecution, and remainder of his liabilities represented general business debts. The fully secured creditors held a bill of sale over the household furniture at Seven Sisters Road. He alleged his failure to have been caused through judgment being entered against him in the actions for malicious prosecution in 1902, to continuous pressure by those creditors, and to the executions levied at his residence, which resulted in his losing a considerable amount of business. His books would show all his business transactions, and his financial position from time to time. His wife had carried on a similar business in her own name, but she was quite able to do so, as she understood the business thoroughly without any assistance from him. None of his goods had been used in his wife's business, and she kept entirely separate accounts for that business. The business was simply one of canvassing for photographs for enlargement. His wife kept all the money she earned. He had never failed before or made any arrangement with his creditors. The examination was closed.

#### NEW COMPANIES.

**HARRINGTON BROTHERS, LIMITED.**—Capital £10,000, in £5 shares. Objects: To take over the business of manufacturing chemists, importers of and dealers in chemicals, drugs, apparatus, photographic materials, oils and colours, carried on by W. B. Harrington, S. Harrington, and I. E. Harrington, at 4, Oliver's Yard, City Road, London, as "Harrington Brothers." The first subscribers are: W. B. Harrington, Lee View, Cork, merchant; S. Harrington, Trafalgar, Cork, merchant; I. E. Harrington, Trafalgar, Cork, merchant; G. A. Cubley, 48, Narcissus Road, West Hampstead, N.W., manufacturing chemist; A. Penzig, 3, Oakley Crescent, City Road, E.C., chemical-warehouse manager; A. Cubley, 48, Narcissus Road, West Hampstead, N.W., surgeon and physician; and M. B. Murphy, 3, Oakley Crescent, City Road, E.C., clerk. No initial public issue. The first directors are W. B. Harrington, F.C.S. (chairman), S. Harrington, G. A. Cubley, A. Penzig, and A. B. Cubley. Qualification £200. Remuneration not less than £10 per annum, divisible. Registered office, 4, Oliver's Yard, City Road, E.C.

**LIFE-SIZE Enlargements.**—We were recently given the opportunity of inspecting at the works of Mr. S. H. Fry, 5, Highbury Grove, London, N., a number of life-size bromide enlargements made by the staff of this well-known firm. Three enlargements 72 x 30 of the same subject we found particularly worth inspecting, as showing the uniform quality obtainable under unfavourable conditions when the work is in skilled hands. The original in this case was a cabinet photograph, which was itself a copy, and we had to confess to no little admiration of the results in all three of the enlargements. Mr. Fry, we saw, has his house in order at his new address, and has made his arrangements for dealing with trade and professional work of a kind that admits of the very rapid and efficient execution of the largest unexpected orders.

In reference to the inquiry of a reader as to procuring the chronoscope of Dr. Miethe's design, made by Bernpohl, Dr. Adolf Heseckel and Co., of 2, Lützowstrasse, Berlin, inform us that they supply the instrument.

**A TRAVEL Exhibition.**—A preliminary prospectus of a travel exhibition to be held at the Horticultural Hall, Westminster, from May 24 to June 3, 1907, has been issued from the offices of the organisers, 75, Chancery Lane, London, E.C. The exhibition is the first of its kind, and is planned on a comprehensive scale. It will include collections of travellers' requisites of all kinds, including photographic equipment. Photography will also figure largely in a section devoted to scenes of travel, and illustrating places and people at home and abroad. The exhibition is to have the moral and financial support of the journal "Health Resort."

#### FORTHCOMING EXHIBITIONS.

September 14 to October 27: The Photographic Salon.—Sec. Reginald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec. J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6 to 13: Bristol Photographic Club.—Sec., J. S. Gubb, 23, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. Hemmingway, Tooker Road, Rotherham.

October 24 to November 14.—West of England Exhibition (Photographic Section). Entries close October 1. Sec., A. D. Breeze, Union Street, Plymouth.

October 31: Watford Camera Club.—Sec., E. H. Jackson, 1, High Street, Watford.

November 7 to 8: Bedford Camera Club.—Sec., W. H. Hodge, Beaconsfield Street, Bedford.

November 7 to 10: Hackney Photographic Society.—Sec., Wal Selve, 70, Paragon Road, Hackney.

November 14 to 17: Rugby Photographic Society.—Sec., R. Myers, 13 Bridget Street, Rugby.

November 15 to 27: Burnley Camera Club. Entries close November 10.—Sec., Fred Whitaker, Mechanics' Institution, Burnley.

November 16 to 21: Southsea Amateur Photographic Society. Hon. Sec., F. S. Hoyte, "Lismore," Stafford Road, Southsea.

November 20 to 23: Sefton Park Photographic Society.—Sec., A. V. Parr, 34, Loudon Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Sec., W. H. Bon, 32, Sackville Road, Hove.

December 6 to 8: South Manchester Photographic Society. Entries close November 21.—Secs., J. H. Haywood and M. W. Thomstone, 43, Lapwing Lane, West Didsbury.

December 11 to 15: Southampton Camera Club.—Sec., S. Kimber, "Oakdene," Highfield, Southampton.

1907.

February 23 to March 2: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. Parnham, "Chagford," Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society.—Sec., J. V. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., Benson, 35, Molesworth Street, Dublin.

**THE American Salon.**—The third American Photographic Salon will be held during 1906 and 1907, in eight cities of the United States and in Toronto. All pictures are to go before a selection committee of 23 photographers, after which six painters will make a further selection from the thousand frames or so picked out by the photographic committee. The painters are John W. Alexander, Joseph R. Woodwell, Martin Borgord, H. L. Hildebrandt, George Sotter, and J. E. Laboureur. The selection committee is composed as follows: Curtis Bell (chairman), Walter Marshall Clute, Sam Holm, Adolph Petzold, Virginia Prall, Helen P. Gatch, William I. Phillips, John Chislett, J. P. Hodgins, Thomas A. Morgan, Oscar Maurer, Wendell G. Corthell, J. H. Field, James E. Underhill, Clarence M. Rodgers, Nellie Coutant, Carl Rau, Louis Fleckenstein, William H. Zerbe, junr., Phillip B. Warren, W. Parrish, H. W. Minns, and R. L. Sleeth, junr. All entries from Great Britain which should be mounted or unmounted, but not framed, should be sent to arrive by October 1st, 1906, to H. Snowden Ward, 6, Farringdon Avenue, London, E.C., England, marked "For Third American Photographic Salon."

## News and Notes.

**R. P. S. EXHIBITION.**—The following is the list of lectures to be given at the New Gallery during the exhibition of the Royal Photographic Society:—

Thursday, September 20: "A Visit to Gibraltar," illustrated with free-colour slides (by the Sanger Shepherd process), and with monochrome slides, by Miss Acland, by special request.

Saturday, September 22: "Wild-bird Life with the Camera," by William Farren.

Monday, September 24: "Five Centuries of Church Building in England," by Henry W. Bennett, F.R.P.S.

Thursday, September 27: "Homeward across the World"—Burma, India, Egypt, and Italy, by A. H. Dunning, F.R.G.S.

Saturday, September 29: "A Dive into Belgium," by W. L. F. Astell, F.R.P.S.

Monday, October 1: "Forest Life." Notes on Natural History with the Microscope and the Camera, by F. Martin Duncan, F.R.P.S.

Thursday, October 4: "Some Spanish Pictures and a Spanish Full-light," by Arthur Marshall, A.R.I.B.A., F.R.P.S.

Saturday, October 6: "Limestone Marvels of the Subterranean World" (the interior of the caves will be shown on a patent crystalline screen, the invention of the lecturer), by F. Lambert, R.G.S.

Monday, October 8: "Our English Chapter Houses," by E. W. Harvey Piper, Hon. M.S.A.

Thursday, October 11: "A Trip to the Victoria Falls of the Zambesi," by John F. East.

Saturday, October 13: "Corsica: the Isle of Unrest," by Chas. Howdill, A.R.B.A.

Monday, October 15: "Bye-paths in India" (Mangalore, Malabar, Cochin, Travancore, Bhopal, the Himalayas, Rajputana, Vizayanagar, and Tadpatri), by F. Dunsterville, F.R.P.S.

Thursday, October 18: "English and Continental Scenes in Colour" will be shown by the triple projection lantern, by Sir W. de W. Abney, K.C.B., D.C.L., F.R.S.

Saturday, October 20: "A Winter Holiday in Greece," by Albert Cheese.

Monday, October 22: "Some Churches of Central France" (details of the architectural features taken with the telephotographic lens), by Ernest Marriage, F.R.P.S.

Thursday, October 25: "All at Sea with a Hand Camera," by F. J. Mortimer, F.R.P.S.

Saturday, October 27: "Winchester Cathedral," by S. G. Kimber. The lectures commence at eight o'clock.

The "Affiliation Night," to be held during the forthcoming R.P.S. Exhibition, has been fixed for September 28. On this occasion the delegates of affiliated societies will meet in the New Gallery, 21, Regent Street, W., in a partly informal way.

**PHOTOGRAPHIC CLASSES** at the Goldsmiths' Institute, New Cross.—The series of classes, under the direction of Mr. W. T. Wilkinson, commences on September 25, a new feature of the forthcoming curriculum being a series of lessons on orthochromatic and three-colour work. It will deal with orthochromatic, photography, its principles and practice; three-colour photography in theory and practice; making and testing the light filters; production of lantern slides, and of prints upon paper in colour, etc. Each lecture will be illustrated either by a practical demonstration of the process under consideration, or by specially prepared lantern slides projected by an electric lantern.

**THE SCOTTISH SALON.**—The committee has decided to run the Salon for three weeks, and close on Saturday, March 16. Societies which may wish to make arrangements to receive pictures direct from the Salon to other exhibitions should communicate with the secretary, Mr. Robert Milne, Linnvale, Potterhill, Paisley. The prospectus is complete, and will probably be issued towards the end of September. The rules and conditions are practically the same as formerly, but with the addition of a rule by which the committee reserve the right to reproduce any of the accepted pictures in the catalogue, the object in view being not, as it were, to steal

the permission, but to save time in making a formal request, which has been hitherto most willingly granted. The Selection Committee will be asked to select the pictures for reproduction. Secretaries of societies will be receiving, in the course of a few weeks, books of tickets for the Art Union, specially promoted for the 1907 Salon. Mr. Norman S. Cochrane, the secretary, has been busy forming his committee, of not less than nine, and carrying through the other requirements of the Board of Trade. The price of the ticket has been fixed at 6d., and prize-winners may select as many pictures as the prize may warrant, and may add to the value of the prize. Purchasers of tickets are reminded that, while an art union is like a bazaar raffle, in respect that you pay your money and take your chance, in the chance lies the difference. The expenses of the art union being nominal, practically the whole amount received for tickets sold is available for prize money. The art union not only provides a means of reciprocating, to some extent, the support given by exhibitors, but, in disseminating the work exhibited, it assists in a most practical way the fulfilment of the aim of the federation in promoting the annual Scottish Salon—viz., the maintenance of a high standard of pictorial photography in Scotland. The Art Union drawing has been provisionally fixed for Saturday, March 9, a week before the close of the Salon.

**INDECENT PHOTOGRAPHY.**—There was a discussion among the magistrates in the Oldham Police Court last week as to whether certain postcards were indecent or not. They represented statuary. Eventually it was decided that they were, and two men who had offered them for sale were both fined, with costs.

**NATIONAL PORTRAIT GALLERY.**—The 49th annual report of the Trustees of the National Portrait Gallery for 1905-6 has lately been issued as a Parliamentary paper (Cd. 3016). The report alludes to the loss the board has sustained through the death of Dr. Richard Garnett, and records the purchases, donations, loans, and bequests during the year. The trustees state that owing to the congested state of the galleries the difficulty of finding space on the walls for the proper exhibition of recent acquisitions continues to increase, and the attempt to maintain a chronological and historical arrangement of the portraits will soon become unavailing. The trustees have been in further communication with the War Office as to the future disposition of the site now occupied by St. George's Barracks, but up to the date of this report no reply has been received from the military authorities. It cannot, therefore, be said that the trustees have any immediate prospect of obtaining the extension of the gallery which has become of such urgent necessity. The number of students who applied for students' tickets during the year was 53, and 58 students had their tickets renewed. The total number of visitors to the gallery during 1905 was 168,769, which showed a satisfactory increase on every day in the week, the total being the largest since 1896, when the new gallery was opened. The total number of visitors admitted on Sunday afternoons during the summer was 13,411, giving an average of 432 per Sunday.

A GREAT photographic exhibition is announced for next year by the "British and Colonial Druggist," which also makes itself responsible for the management.

**BIRMINGHAM PHOTOGRAPHIC SOCIETY.**—The date of the next annual exhibition has been fixed at February 27 to March 2, 1907.

**THE MEMBERS' DINNER** of the Royal Photographic Society is to be held on Tuesday, September 18, at the Holborn Restaurant. The date is the night before the private view and soirée of the New Gallery, and it is hoped that many provincial members of the society will be present. Applications for tickets should be made to Messrs. Leslie E. Clift or A. W. W. Bartlett, the stewards.

**INSTRUCTION IN PROCESS.**—The twelfth session of the London County School of Photo-engraving and Lithography commences Monday, September 24, 1906, when the following courses of instruction are open to all engaged in the printing, designing, photographic process, illustrative, and lithographic crafts:—Photo Engravers—Line and screen negative making, etching, proving, tricolour work, photo-gravure, and preparation of originals for reproduction. Photo-lithographers—Negative making, photo-lithography, collotype (plate preparation, press and machine work), combinations of lithography and collotype. Photographers—Line and continuous tone negative mak-

ing, printing, enlarging, transparency making. Lithographers—Lithography, map and plan drawing, transfer writing, drawing, design, lettering, photo-lithography. Designers.—Design, drawing, lithography. Draughtsmen.—Drawing, design, lettering, pictorial composition.

Of particular interest to photographers at the present time should be the course of three lectures on "The Theory of Photographic Processes concerned in Negative Making," by Mr. C. E. Kenneth Mees, B.Sc., F.C.S., the syllabus of which is as follows:—The laws of absorption—the exponential law—the relation between absorptive power and the mass of substance present—the relation between exposure and density—Hurter and Driffield's researches—practical sensitometry and the instruments employed—exposing instruments—developing thermostats, photometers. Development—the relation between time and density—the theory of alkaline development—the theory of fixation—colour sensitometry and the measurement of colour filters. These lectures commence on May 9, 1907. There is also a course of four lectures on "Three-Colour and Orthochromatic Photography," by Mr. A. J. Bull, to commence on June 6, 1907.

During the winter session a series of Thursday evening lectures is given on different subjects in the School, admission to which may be obtained on application to the Principal of the School, Mr. A. J. Newton. The following is the programme of these lectures:—November 22, 1906—A. J. Newton: "Commercial considerations in Photo-Engraving." November 29, 1906—Arthur Coles: "Accounting and Economics of Photo-Engraving." December 7, 1906—E. F. Strange: "Artistic Lithography—the Revival." December 13, 1906—T. R. Way: "The Production and Printing of Artistic Lithographs." In the second term.—January 10, 1907—J. Murray Allison: "The Artist and the Advertiser." January 17, 1907—A. H. Tinkler: "Etching Proper, Photomechanical Etching and Fine Etching." January 24, 1907—B. J. Hall: "Fertile and Heliographic Processes." January 31, 1907—Alfred Coe: "Recent Improvements in Collotype." February 7, 1907—O. S. Dawson: "Photographic Printing in Natural Colours." February 14, 1907—Wm. Gamble: "Business Methods of American Photo-engravers." February 20, 1907—Edward Johnston: "Caligraphy." February 28, 1907—Frank Colebrook: "The Illustrative Arts in Recent Exhibitions." March 7, 1907—W. B. Dalton: "Some Notes of English Caricature." March 14, 1907—Joseph Pennell: "Tendencies of Modern Illustration." March 21, 1907—E. W. Foxlee: "Powder Processes in Photography." The full prospectus of the school, giving particulars of the courses of instruction and the fees (nominal), is sent on application to the Principal, at 6, Bolt Court, Fleet Street, London, E.C.

MR. E. L. WHITE.—We learn that Mr. E. L. White, managing director of the Photochrom Company since its formation has resigned that position.

ATTEMPTED SUICIDE.—A photographer named Hyatt, of Kew Green, was charged at the Kingston County Bench last week with attempting to take his life by swallowing a quantity of laudanum. The prisoner had previously been brought up on a charge of arson, and he had been convicted for an assault in a railway carriage. He was remanded.

THE premises of Mr. Arthur Simmons, photographer, of 258, Westminster Bridge Road, were broken into on September 2 by Arthur Jeffcott, a labourer. At the Tower Bridge Police Court, Detective-sergeant Beard, L division, said the prisoner got into the house by squeezing through a window which measured 16in. by 12in. He was only able to steal 12s. 6d. and two bunches of keys. The prisoner had undergone four years' penal servitude for arson. He was committed for trial.

SOCIETY DEMONSTRATIONS.—Messrs. John J. Griffin and Sons inform us that they are now completing arrangements to give demonstrations during the winter session on either of the following subjects:—(1) Velox and its manipulation. (2) Enlarging simplified. (3) The theory and practice of self-toning papers. Secretaries of societies should address them at Kingsway, London.

THE SCIOPTICAN CO.—A correspondent informs us that the present address of the company is Mrs. Smith, 38, Portland Road, Finsbury Park, N.

FLAMANK AND TOWNSEND.—We are in receipt of a notification from 69, Whitehead Road, Aston, Birmingham, to the effect that the above partnership has been dissolved, and that the business be continued at the same address under the style of "Flamank Photographic Works."

THE Proposed Paris Exhibition.—"Truth," in a recent issue publishes the following: "The following experience of mine seems to have been an impudent swindle is related by a gentleman who was last year awarded the medal of the Royal Photographic Society for certain tricolour photographs. Early in the present year he received a letter inviting him to send these photographs to Paris for exhibition. The letter had the printed heading 'Deuxième Exposition Internationale de la Photographie et des Arts, Sciences, et Industries qui s'y rattachent. Paris, Grand Palais des Champs Elysées. Téléphone 709-84.' It was signed 'Le Commissaire Général, L. Gastine.' Believing this to be a genuine affair, the owner of the photographs forwarded them together with a small fee that was demanded for space for exhibition. No acknowledgment reached him, but in June a letter came intimating that the exhibition was postponed till next year. This letter had the same heading as before, but stamped at the bottom it was a new address, 'Bureaux, 13, Avenue de la Motte, Piqueux, Paris.' The signature was 'p.p. le Commissaire Général, Charpenet.' Applications were at once made both by letter and telegram for the return of the photographs. These communications, however, were not answered, and subsequent inquiries in Paris have elicited the information that the whole thing was a fraud, and that the parties who carried it out cannot be traced. It will probably be found that many other persons have been victimised in the same way. No doubt the dating of the first letter from the Grand Palais facilitated the fraud, and it is to be hoped that the authorities there will in future take better care that that address is not used by swindlers."

The gentleman referred to in "Truth" is, of course, Dr. D. H. Hutchinson, of Lowestoft, the recipient of a medal last year at the exhibition of the Royal Photographic Society. Since the paragraph appeared in "Truth," Dr. Hutchinson, so we learn from him, has had his slides returned to him. He writes to us that he cannot tell you who it was that returned them to me, as there was no communication enclosed. Whether the post office officials find that there was no responsible person to receive them at the Grand Palais (the slides being insured for £20), or whether the Grand Palais, Gastine, found that the slides were of no value to him and returned them, I am unable to say. My own impression is that the first theory is the correct one. Although I have recovered my slides I have not received back the monies I paid him, and we have made inquiries in Paris, through a friend of mine, I was told that the whole concern was a fraud, and no trace could be found of Gastine." Dr. Hutchinson also sends us a letter written to him by M. Gastine on the receipt of the three-colour transparencies, the tenor of which does not say much for the way in which the management of the exhibition was conducted.

"Paris, le 2 Mars, 1907"

"Monsieur Hutchinson,  
"35, High Street, Lowestoft,

"DEAR SIR,—I have just received your postal order of ten francs concerning the duty of inscription.

"Your 'lantern slides' can take place as well in the Group X as in the Group X.

"Concerning the Group II, it seems to me less certain that they can be admitted specially, because they do not depend of any scientific work well determined.

"The necessary implacement for your sending is indeed very particular. I will take the necessary dispositions in order that your 'lantern slides' will be well lighted, but it will be necessary for that to consecrate three feet (un metre) at less on 'cimeaise' on about six feet (two metres) high; which loose a pannal of 3 pounds (75 francs) which I will have reduced specially, in rapport of the interest of the sending itself, at 50 francs (two pounds), payable only after that you have received in few weeks your certificate of admission.

"Thanking you for your kind contribution, please accept, dear Sir, my kinds regards,

"LE COMMISSAIRE GENERAL,  
"M. L. GASTINE."

## New Books.

London, a Guide to, for the Visitor, Sportsman, and Naturalist." gives us in its second edition, with corrections and additions, which make it a most commendable guide to the stranger in the metropolis. In pocket size, and the conciseness of its information, are welcome changes from the more bulky guide books. The price of the book is 1s., and the publishers are Greening and Co., 20, Cecil Court, Strand, Cross Road, London, W.C.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE P.P.A. AND ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—Referring to the correspondence re incompetent assistants, it is curious to find how very few professional assistants attend the various photographic classes or lectures during the winter months. In an ordinary photographic business nothing can be learned beyond printing, toning, and a little bromide printing. At the classes every process is worked in its turn, with full explanation of failures and remedies. Experiments can be made under the best conditions, opportunities are given for enlarging, for orthochromatic work, and for proving its utility; everything done is done with thoroughness, and with a full desire to help the learner and the expert.—Yours faithfully,  
AN OLD PHOTOGRAPHER.

London, S.E. August 28, 1906.

### THE ZANDER FOUR-COLOUR PROCESS.

To the Editors.

Gentlemen,—Much as I dislike controversies in public journals, I cannot permit Baron von Hübl's erroneous criticism of my four-colour process to pass unchallenged.

First of all, Hering's theory does not apply to my process. Moreover, Hübl's colour circle does not agree with my researches, and, therefore, the trapezium in which he makes my colour system appear against the square formed by the colours that he advocates need not be taken seriously, particularly as judging from my practical experience I feel convinced that his four colours would not produce the results he would desire.

The four fundamental colour agents—magenta, lemon-yellow, emerald green, and ultramarine blue—were selected by me, after very careful and lengthy experiments, and are true complementary colours, as they produce the sensation of white when optically superposed in due proportions, and black or grey when combined mechanically as pigments. Baron von Hübl is absolutely wrong in his dogmatism when he asserts that "when, however, a four-colour photograph is attempted by this method, it will soon be seen that the expected result cannot be obtained, for dirty colours will always be obtained." My process is being worked commercially, and the beautiful results obtained are entirely at variance with the latter statement. There is not the slightest doubt about a four-colour scheme, such as I devised, reproducing colours not only far brighter than three-colour work, but also the range of colours obtainable is far more extensive and accurate.

The reason of Baron von Hübl's misleading dogmatism is not far to seek. I can readily see his errors in his diagrams; but it is not of my business to set him right. I have always had the highest respect for Baron von Hübl and his work, and, therefore, can only assume that his four-colour theory has little or no foundation in actual practice or research, or that the latter had stopped short of having been brought to a satisfactory and practicable conclusion.

I would also point out that although Baron von Hübl condemns four-colour work in his article as unworkable, and has also done so in his book, "Die Dreifarbenphotographie" (page 77), he would yet lead us to believe that it has been practically worked, and that I have only endeavoured to re-introduce it. I take strong exception

to such a statement, for I have hitherto failed to discover any examples of a practical working of a four-colour process, either on my own plan, or any other system (except the well-known four-colour scheme of yellow, red, blue, and grey or black). My process is not identical with, or a re-introduction of, any previous photo-mechanical colour reproduction process, but is based on independent and original research, and the outcome of lengthy and patient work and study.—Yours faithfully,  
C. G. ZANDER, F.R.P.S.

15, Whitefriars Street, London, E.C., September 3, 1906.

### FACTORIAL CALCULATORS.

To the Editors.

Gentlemen,—In the factorial calculators you illustrate in your last issue, a separate instrument has to be made for each factor. Thus, a cardboard calculator made for metol (factor 30) would be of no use for any other developer.

There is no need for this limitation, and in the aluminium factorial calculator we issue (the first instrument for the purpose made), the one instrument serves for calculating with any factor, and there are no more figures marked on it than in the ones you illustrate. It is only necessary to point an arrow to the factor used, and the instrument is then set for that factor, the time of development being read against the time of appearance. The division of the circle into 60 parts makes this possible, as seconds' appearance are automatically translated into minutes' development.—Yours truly,

WATKINS METER CO.

Imperial Mills, Hereford, September 1, 1906.

A REPRODUCTION of a portrait of the late Henry Martyn Jeffery, F.R.S., has been skilfully executed in platinumotype by Messrs. Holloway, of Cheltenham, and forwarded to Budapest, Hungary, to be added to the collection of eminent mathematicians at the University of Budapest. The late Mr. Jeffery was headmaster of Cheltenham Grammar School from 1868 to December, 1881.

At Exeter Police Court last week, James Morton, photographer's canvasser, was charged with embezzling 18s. from his employer, Chas. Cox, a travelling photographer, residing at Friar's Walk, Exeter. He was sent to prison for a week.

PUBLIC Taste in Photographs.—Perhaps there is no branch of art practice (says the "Globe") which shows as plainly as does photography how dangerous is the influence of the illiterate patron. Of all the forms of art expression, photography is the one which will give most perfectly and most completely the subtlety of nature, the one which in its absolute exactness of tone can reproduce all the elusive refinements of atmosphere and light and shade. Yet it is the one which is most persistently used to satisfy the ignorant demand for falsity of effect. The photographs which people prefer are those which are least like nature in their exaggeration of tone contrasts, in their want of right gradations, and in their perversion of nature's facts; and, as a consequence, our illustrated magazines are filled with reproductions of photographs which represent the lowest possible type of achievement and the unworthiest form of art. But such is the density of the public misunderstanding of the elementary principles of artistic effort that no protest is ever heard against this prostitution of illustration or against the indifference of the directors of those magazines to all æsthetic considerations.

HUMOURS of the Shop Counter.—Photographic dealing is not without its humorous side, yet we doubt if it could present such a crop of curious blunders as that sent to the "Chemist and Druggist" by a Tasmanian correspondent. A few are: "Opol pills," "iron and hallow pills," "Pacific oiniment," "magneesher," "boricatic ointment," "beatcham pills," "parry goric," "oxaric acic," "sweet niter kuibic and bawlsom compbive," "bensean," "licer's powder," "black dimon die," "proxiden," "genison" and "gensing," "Iredine" and "hydyne," "philerdofler" and "adol-plus," "white heather black oil and heartsorn," "a cheap enimer." A request for "1 Bottle Scothelum" requires inside knowledge, Scott's emulsion being intended. The same might be said of "Eclat with wine"; in this case a catheter was meant. A rather quaint order was for "a glass chube that go in a suck bottle." But, as at home, the orthography of hiera picra was the main trouble. Mr. Hinsby's clients spell it variously as "Hikery pirkey," "ikpriky," "Ikery pikery," "icory picrory," and "ickrepickey."

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- J. Phillips & Sons, High Street, Biggleswade. *Photograph of a Goat Suckling a Foal.*
- H. Linn, 36, Taylor Street, Woolwich. *Photograph of J. Ashcroft, Goalkeeper of Woolwich Arsenal Football Club.*
- W. T. Whiffin, 770, Harrow Road, Willesden. *Photograph of Queen's Park Rangers Football Team.*
- J. Jarrett, Ewart Lodge, Jameson Road, Bexhill, Sussex. *Two Photographs of Elephants.*
- W. Smith, 35, New Road, Grays, Essex. *Photograph of Grays Beach.*
- S. H. Greenway, 27, Abington Street, Northampton. *Photograph of the Northampton F.C. (Association, Southern League).*

MEMO.—In our next.

P. B.—If you are engaged at a weekly notice we do not see that you can claim anything for wrongful dismissal, nor can you if, in the absence of any definite arrangement, you were paid weekly. If the firm refuses to pay for the overtime and retouching which you have done you can sue them for these amounts, provided you can prove that they are due to you.

COPIES ON LINEN.—Would you explain to me through the columns of your valued journal, how, by a photographic process now in use, copies of builders and engineers' plans can be produced on linen, also where can the necessary materials be obtained?—H. F. WILLS.

You can obtain sensitised linen for ferro-prussiate copies from any of the regular houses, such as J. R. Gotz, 211, Shaftesbury Avenue; Marion and Co., Soho Square, W.; or Allott and Jones, Liverpool.

REVERSING MIRROR.—I should be grateful if you would tell me how to make or where to purchase such a 45 deg. mirror as you mention for street photography in "Ex Cathedra." Will there be no secondary image from the front surface of the glass if glass is used? And it looks as if speculum metal would be as costly as a prism.—Q. S.

Any optical firm, such as W. Watson and Sons, 313, High Holborn, London, E.C., will supply you with a mirror. It should be silvered on the glass side, and there can then be no secondary image. Instructions for silvering a mirror will be found in the ALMANAC.

DARK ROOM LIGHT.—Can you kindly give me, through your "Answers to Correspondents" column, a formula for a solution for a "bichromate" dark room lamp which will give a safe light with Imperial "Special Sensitive" plates? I want a single solution which will give the same results as when a methyl violet stained gelatine screen is put in front of the bichromate solution. The lamp I want to use the solution in is circular, and it is not convenient to use a stained gelatine screen. The solution will be 3/4 in. thick. I have looked up all the formulae I could find in back numbers of the photographic journals and books, but cannot find a suggestion for a solution to give the result referred to. The nearest seems to be that suggested in the "Amateur Photographer," October 11, 1901, page 298, of rhodamine mixed with bichromate solution, but I do not think this cuts off far enough into the red to be safe with the plates mentioned. I have some doubts as to whether rhodamine will mix with bichromate solution, but I have not tried it. What is the best solution you can suggest?—S. C. PUDDY.

We should advise you not to mix a dye solution with the bichromate, since the oxidising character of the latter will very

probably result in the alteration of the colouring matter, if at once, at any rate, in time. And there is no necessity to employ the chromate as the results you require may be secured by a mixture of dyes. We should advise you to prepare a solution as follows:—Fast red, .25; flavazine, .5; methyl violet, .25. The quantities of each dye in the above formula are in milli-grammes per cc. that is to say, if your cell holds 200 cc. you will require .05 of a gramme of fast red. All the dyes are water-soluble, and can be obtained from houses such as Fuerst Bros. or Mawson and Swan.

STUDIO BLINDS.—I am thinking of having new blinds to my studio. The sun shines on the skylight most of the day, and what you have does not seem opaque enough. What would you advise? I thought a row of white on rods to knock along—nearest to the glass—and then underneath these a row of black or dark green. I want something almost or quite opaque in this way. Can you give me information I shall be glad of. In buying material you advise what shall I ask for?—N. N.

We should recommend you to have dark green blinds in preference to black, as they will give the studio a less somber appearance than the black would do. If you have the material thick enough it will be practically opaque. What is known as twill is a suitable material and is very inexpensive.

TONING P.O.P.—(2) Have been going to write you before to see if you can tell me what enclosed substance is? It is one of the formulas for forming a cheap toning solution for post cards put up by a local chemist. He says it is not lead, the others are hypo, alum, and when mixed, throws down a black deposit like black lead. (3) It gives a nice tone and fairly permanent, but still the face of the card. Can you give me a cheap formula which would not stain, and fairly permanent?—P. T.

(1) We cannot say. Your best course would be to address the local newspaper from which you might ascertain the address of the deceased lady's friends. (2) From the minute sample we can only say that it is an acid, probably oxalic or some other organic acid. Either of these with the hypo and alum will form a sulphur-toning bath; a mixture which we strongly countenance for toning purposes. (3) We may, however, give you a formula of which a correspondent who gave it in issue of June 1 last spoke well as regards permanence of results. After well washing and immersing in a solution of alum and salt (the Ilford formula) the prints are again well washed and toned in hypo, 3ozs.; water, 20ozs.; glacial acetic acid, drop.

SPOTS ON P.O.P.—We should like to know your opinion as to what is the cause of spots on enclosed blotting paper. The enclosed is "Fotonic" paper, and directly wet prints are placed on it, they appear in a short time and thus on to back of prints, stain through. We put same down to chemicals in the air, but since we have removed washed prints and blotting paper into another room away from all chemicals they still appear. And I state that fresh paper, such as enclosed, is always (and always been) kept away from all such things.—G. B.

We must confess we are at a loss to explain the cause of the spots. They certainly look to us like the results of dust of hypo or amideol from the air. Perhaps some of our readers who have had a similar experience can give a hint as to the cause.

\**NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.*

## SUMMARY.

The Photographic Salon opens to-day (Friday) at 5A, Pall Mall East, No. 130, Mr. George Bernard Shaw, photographed in the studio by Mr. Coburn, has created something of a sensation in the daily press. (P. 724.)

Members of the P.P.A. are asked to notice the approaching exhibition at the BRITISH JOURNAL. (P. 721.)

Toning P.O.P. postcards on the wholesale scale. Mr. G. T. Harris explains the methods found by him to be efficient and economical. (P. 725.)

The special methods to be followed in working-up platinotypes are the subject of some notes by Miss M. P. Bell. (P. 729.)

MM. Lumière have recorded their good opinion of alum *plus* sulphite in the fixing bath as a means of tanning the gelatine film. The same two chemicals in the combined toning and fixing bath will prevent P.O.P. troubles in hot weather. (P. 727.)

Recent lectures by Prof. V. B. Lewes have laid stress on the importance of fire-preventive measures and on the value of fireproofing materials. (P. 722.)

A photo-engraver has taken up the recent article of Mr. F. C. Tilney championing the foreign maker and printer of three-colour engravings. (P. 728.)

Fallacies of stereoscopic vision are the subject of an editorial in reference to the recent paper of M. A. Goderus. (P. 723.)

An exposure of coupon frauds, which were recently being practised by a man in the suburbs of London, under the name of a Bond Street photographer, appears on page 733.

An exhibition of photographs by Mr. S. L. Coulthurst is being held at the rooms of the Manchester Amateur Photographic Society. (P. 734.)

## EX CATHEDRA.

### The P.P.A. Exhibition at the "British Journal."

During the past few days we have been in receipt of a number of letters in reference to the exhibition of photographs by members of the Professional Photographers' Association which, on October 11, is to succeed the present show of portraits by the Camerons, mother and son. As some of our correspondents appear not to have perfectly realised our intention in suggesting the exhibition, we would repeat that it is desired that the one photograph which each member of the P.P.A. is entitled to exhibit should represent the work as ordinarily produced in his establishment, not special work or photographs of specially attractive subjects. The conviction which prompted us to suggest the exhibition to the P.P.A. is that photographers cannot help benefiting by seeing the kind of production which their brethren in other districts are producing, and that this simple and friendly act will, at the same time, be a step towards those ideals of co-operation which are yet a great way off. Therefore it will only be to defeat the aim of the exhibition if work of a special character be contributed. We are in hopes that there is still time to clear up a misconception which exists possibly in other minds than those of our correspondents. Eleven days yet remain before prints need be despatched to our offices. Will members of the P.P.A., who have not yet sent a print, make good use of the time?

### An Exhibition Without Rules!

Save only as indicated in the above paragraph, there is a delightful absence of rules as to the holding of the exhibition. There is no selection. Every exhibitor sends one print, and every print sent in will be shown. We imagine that the great majority of the prints will be portraits, but portraiture need not necessarily be the subject. Photographers whose work lies in the reproduction of articles of manufacture in marine or engineering photography are equally entitled to represent themselves as are the portraitists. The exhibitors, as we have said, are limited to members of the P.P.A., but the exhibition will be opened to all during the hours frequently announced in these pages. It will close on November 10.

### Ammonium Sulpho-Cyanide.

Some readers of a pharmaceutical contemporary are expressing discordant views on the necessity or otherwise of complying with the Poisons Act in the case of ammonium sulphocyanide. The wording of the Poisons Schedule is open to misconstruction, yet we do not think that the sentence "all metallic cyanides and the preparations of such

articles" can be taken as including the sulphocyanides which are distinct chemically from the cyanides, and are no more subject to the Act than the ferrocyanides and ferri-cyanides, which are everywhere sold without question. In fact, the Schedule expressly mentions mercuric sulphocyanide in Part II., and thus implies that the sulphocyanides of the alkalis are not regarded as scheduled poisons. This, if we are not mistaken, was also the specifically expressed opinion of the Pharmaceutical Society some ten or fifteen years ago, the pronouncement having been prompted by the Ilford Company, who were at that time popularising the sulphocyanide toning bath for their newly introduced printing-out paper. So far as we know, nothing has since transpired to affect the sale of sulphocyanide.

#### Ordering Plates.

Messrs. Houghtons, Limited, in their current "Monthly," are again drawing attention to a form in the ordering of plates which it is certainly advisable should become a custom in the trade. It is the use of the word "packet" instead of "dozen" when ordering plates. When the latter expression is employed there is the doubt in the wholesaler's mind as to whether it refers to the plates or the boxes, each containing one dozen. "Send me four dozen  $\frac{1}{4}$  Ilford Monarchs" may be four dozen plates or four dozen packets. Messrs. Houghtons' suggestion that the word "packets" should become established may be commended to the trade. It should absolutely prevent the mistakes which result from the ambiguous use of "dozens."

#### Fire Risks.

A valuable series of Cantor lectures by Professor Vivian B. Lewes, delivered before the Society of Arts in the spring, has now been completely published in the Society's "Journal," and will doubtless be issued, as other Cantor lectures, separately, in pamphlet form. Professor Lewes dealt with the many aspects of his subjects, yet did not overlook the importance of preventive measures which may be taken by small householders or by proprietors of photographic studios. The chief value, he pointed out, of the modern methods of rendering timber non-flammable, lay not in the protection of structures or articles composed of it, but in the fact that such impregnated timber is only charred by intense heat. It will not flame, and therefore is unable to spread the combustion. Very many substances had been proposed as efficacious in imparting non-flammable properties to timber, but Professor Lewes' experiments had

narrowed down the list to ammonium chloride, ammonium phosphate, ammonium sulphate, calcium chloride, cesium chloride, zinc chloride, zinc sulphate, stannous chloride, alum, borax, boracic acid, and aluminium hydrate.

#### Fire-proofing Fabrics.

The assistance which curtains and other loosely arranged fabrics render to the spread of even the smallest conflagration is so frequently the factor which converts a tiny outbreak such as the overthrow of a lamp, into a serious fire, that Professor Lewes' counsel as to the fireproofing of fabrics should be accorded the consideration of all tenants of photographic establishments. Just as in the case of timber, curtains or backgrounds are not themselves rendered immune to the action of a flame, but if saturated with a solution of ammonium phosphate and borax, which is as good a fireproofing preparation as any, their capabilities as conveyers of the flame are practically destroyed. Professor Lewes has also some words of advice to householders on the valuable protection offered them in various "extincteurs" and grenades, which act on the principle of disengaging gases which are non-supporters of combustion, just as a handful of sulphur thrown on a grate will extinguish a chimney on fire by its evolution of sulphurous acid gas.

#### September Photography.

A month of clouds and soft lighting. September was looked upon by many as the best month in the whole year for outdoor work. The majority of the work of the late Mr. Vernon Heath, for instance, which it would be difficult to beat now—although there was no orthochromatic photography in his day—was done in September. The glorious tints on the landscape at this season are not to be seen at any other time of the year, and orthochromatic photography places in our hands a means of reproducing them in a way that was impossible at one time. The light, it is true, is not of the same actinic value that it was a couple of months or so ago. But the exposures necessary are not proportionately so much longer now than earlier in the year, as the shadows are longer and the light much more diffused, even when the sun is at its highest. When the sun is near its zenith the shadows are short and very strong and deep, and, as a consequence, a comparatively long exposure is necessary to obtain detail in them. At this season the conditions are different, the shadows are weaker and more transparent

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, so as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

and there are usually light fleecy clouds about that greatly aid in diffusing the light, so that, in practice, although theoretically the light is really not so strong, a very little extra exposure is necessary beyond what was required at midsummer. To best render the gorgeous tints now to be seen in the landscape a screened orthochromatic plate should be employed, and should be backed to avoid halation.

\* \* \*

#### Photography and the Boat Race.

At no previous race on the Thames was photography so much in evidence as it was at the contest between the Cambridge and Harvard Universities on Saturday last. Cameras of all descriptions were to be seen in every direction; indeed, at some points on the towing path almost everyone seemed to have cameras. The weather and light were all that could be desired for photography, and it would be interesting, if it were possible, to know the number of plates and films that were exposed on the occasion, and what proportion of them proved satisfactory pictures. However, it must have been a good day for the plate and film makers. As an illustration of the enterprise of those who produce cinematograph pictures it may be mentioned that the two crews finished up the day at the Alhambra, where at 10 o'clock they were enabled to see animated pictures of themselves competing against each other only five hours before. Animated pictures of the boat race were also shown at other music-halls the same evening. It is obvious that not much time could have been lost in the production of these pictures.

\* \* \*

#### Odd Jobs.

It not infrequently happens that a photographer, whose main business is portraiture, is called upon to do something out of his usual rut, as, for instance, to photograph articles of manufacture, and he finds himself at a loss how to proceed in order to secure what is required. That such is often the case is clear to us from the queries that are continually reaching us for information. These usually come from photographers in small provincial towns in which there are few facilities for seeing good work of a special kind, or gathering hints on methods of procedure. The majority of skilled portraitists can apply their knowledge to almost any requirements of the art, but to those unable to do so we commend the notes on "Commercial Photography" which appeared on pp. 706-7 of our issue of last week. From these the inexperienced in what is termed "commercial photography" may gain some very useful hints which they should have no difficulty, with a little modification, in applying to any work they are likely to be called upon to execute. We do not say that the information there given will meet every case, but there is enough, with the exercise of some little ability, to accomplish satisfactorily anything that may be required out of the general run of portraiture.

### STEREOSCOPIC TRUTH.

The paper by M. A. Goderus, a translation of which we published in our issues for August 17th, 24th, and 31st, forms a very interesting contribution to the literature of stereoscopy, but we cannot say that all the conclusions of the author can be justified by the theory of stereoscopy, or even by the evidence he has himself advanced. It therefore appears to us very desirable to put before our readers, in somewhat different language, the real conditions that govern true stereoscopic effect.

The fundamental law governing the truth of the effect observed is that all parts of the images shall be seen at the

same angle of convergency as that at which they were produced. Provided that this law is fulfilled, then the form and relief seen in the stereoscope is absolutely true, even though the apparent size and distance of the subject may vary. M. Goderus seems to consider that truth of stereoscopic effect involves also true apparent size and apparent distance, and, from some of his remarks, appears to suggest that if these two conditions are not fulfilled the apparent relief produced is false. It is hardly fair to criticise his statements from a translation, and it is possible that he did not intend to convey this impression, but it is certainly suggested by his remarks on page 690, and as any such idea is quite contrary to facts we feel bound to try to dispel it.

If a pair of stereoscopic views is taken with a lens separation greater than that of the eyes, and is viewed with strict observance of the law of equal convergency, then the impression produced is, as M. Goderus states, that of a view of a subject that is both smaller and nearer than in nature. In other words, it is a view of a small model of the original, but M. Goderus has omitted to point out that this small model is an absolute replica of the original, corresponding with it in every respect, excepting in matters of apparent size and distance. Suppose the original to be a true cube with bas-relief on its sides. Then the image seen in the stereoscope is that of a true cube, smaller than the original, and nearer to the observer, and, on account of this nearness, the relief of the carving is slightly more obvious and bolder than it would appear in the original at its actual distance. This effect is produced in M. Goderus' fig. 13, and is a proof of the truth of the results obtained with widely separated lenses, though he appears to take it as a proof of inaccuracy. If an object appears in the stereoscope to be nearer than its real distance, the relief should appear to be greater, while if the object appears to be at a greater distance the relief should appear flatter, just as it does in the examples given.

The fact that widely separated lenses produce results that, viewed correctly, give an absolutely true impression of everything except apparent size and distance, is a most valuable feature of stereoscopy, for a close view of a small exact replica of the subject is in the majority of cases precisely what is desired. Truth of apparent size and distance is easily attained in theory by making the separation of the lenses equal to that of the eyes, but the advantages of so doing are much over-estimated. In the first place, the result shows no more than can be seen by inspecting the object itself, and the advantages of a near view are lost; and, in the second place, the truth of apparent size and distance will meet with no appreciation whatever, excepting, perhaps, in the case of portraiture, which is hardly a suitable subject for stereoscopy in any case.

M. Goderus has seemingly forgotten that apparent distance is a most deceptive matter, while under the laws of vision apparent size is a variable quantity, differing according as we use direct or indirect vision. If the relative sizes and distances of different portions of the subject are correctly represented (as they are if the law of convergency is fulfilled, however far the camera lenses may be separated) we attain as much in the stereoscopic view as we can wish for. Errors in apparent size and distance cannot be detected except in most unusual circumstances, for both qualities are, at the best, vague and indeterminate.

With very near objects the separation of the lenses *must* be decreased for two reasons. First, because if the separation is too great, the prints cannot be mounted so that the law of convergency is fulfilled; second, because with a too wide separation the two images cannot be brought on to the plate. These difficulties may be overcome by using a special kind of stereoscope, and taking the negatives in two separate converging cameras, but the results are not worth the trouble excepting in very special and unusual cases.

The reference to converging cameras reminds us of an error made by M. Goderus that we are surprised to see in a paper that represents so much thought and experiment. It is an old-established error to suppose that converging lenses and cameras have any particular advantages over the ordinary form, excepting in the particular case we have mentioned. Given correct viewing conditions, the results attained by using parallel lenses and image surfaces in one plane are identical with those produced by converging lenses and plates at right angles with the axes of the lenses. This must be apparent to anyone acquainted with the laws of plane perspective, yet the idea that converging lenses will give truer effects is a myth that has deceived many writers other than M. Goderus. Another common myth is that images produced with widely separated lenses necessarily show exaggerated or distorted relief. As we have endeavoured to show, they do nothing of the sort if the results are viewed with the proper angle of convergency, but if the law of convergency is not observed distortion at once appears. To fulfil this law the prints must be correctly mounted and viewed at a proper distance, but so long as photographers are content to observe no rule of

mounting at all, and study in long-focus stereoscopic views made with short-focus lenses, distortion will continue to be an obvious defect in the great majority of stereoscopic views. The stereoscope lenses should be of approximately the same focal length as the lenses used in the camera, whereas they are very commonly of twice that length. The correct rule for mounting is given in an "Cathedra" note, and need not be repeated here. The rule does not appear to be generally known, and so-called "rules" often observed are usually only correct in certain specified conditions that are seldom mentioned in point is the "rule" laid down by the International Congress that is justly criticised by M. Goderus.

We may observe, in conclusion, that the true effects produced by viewing objects from points more widely separated than the eyes are best studied with the aid of the tele-stereoscope. A few experiments with this simple instrument will soon convince anyone that distortion, exaggerated relief, is not a consequence of wide separation, in spite of the unusual conditions, objects presented in their form perfectly, even when viewed from points separated by several feet.

## THE PHOTOGRAPHIC SALON.

### A FIRST IMPRESSION.

At the moment of going to press we are able to anticipate our review of this exhibition by giving a general notion of its character. Next week we shall go more particularly into criticism.

In the first place, the press-men, if not the public, are pleased to find that there are about seventy pictures fewer than there were last year. This, one would think, might result in a higher average of merit; but the facts do not bear out such an expectation. There have been shows that have surpassed this one in general interest. The men of repute have not made an effort to enhance their reputation, except in the case of Mr. Horsley Hinton, whose two pictures are, we consider, more fresh and more artistic than usual. To the lesser known names, however, the exhibition is most indebted for its attractions. We welcome the work of Eduardo Garrone, who is a newcomer, and whose influence promises to be valuable. The highly artistic and decorative pieces of F. Benedict Herzog, whose "Isolde" last year made a sensation, stand out in work of a higher order than is usual amongst photographers with leanings in this direction.

The greatest sensation of all, however, will prove to be the portrait of Geo. Bernard Shaw—the ubiquitous. We call it a portrait because, in that guise, it arrests attention. The catalogue calls it "Le Penseur," which is the name of a much-talked-of statue—larger than life, though not so natural as this—by the French sculptor, Rodin. Mr. Shaw has very cleverly adopted the pose of this statue, and although, were the two versions compared, a wide difference would be noted,

yet his aptitude for "living pictures" is clearly demonstrated. We are surprised at nothing done by G. B. S., and therefore we can remain calm as we regard his self-respect thus butchered to make a Salon holiday. This diverting photograph is by Alvin Langdon Coburn, who, with characteristic prolixity, has eight works on view. We think "The Rudder, Liverpool," his best utterance. His own portrait is given by both Bar A. de Meyer and by Reginald Craigie. Both are striking works, but, curiously enough, do not look like portraits of the same sitter.

Walter J. Clutterbuck delights us with his fine sense of style and his good feeling for natural light. Similar praise due to Arthur Marshall for his Venetian subjects.

Fredk. Hollyer's portrait of A. Horsley Hinton cannot be regarded as a speaking likeness.

Of Mrs. Käsebie's works we prefer "Josephine." She has sent two early Victorian costume subjects, of which one is ineffectively tinted—by hand presumably.

Percy G. R. Wright has done extremely well with his "Truants," two youngsters being marched along by a peasant woman in a Continental street. And when we have named "The Bridge," by Alex. Keighley, and "Late Afternoon," by Charles Job, we have touched upon the chief works that remain in our minds as good things after leaving the galleries.

It does not follow that there remains nothing else good. On the contrary, work by Mr. F. H. Evans, Rudolph Dührkoop, and many others is as good as we expected of such past masters, and therefore they make no unusual impression.

**BABY'S Singular Death.**—An inquiry was held last week concerning the death of a seven months' baby. The mother said the child had his photograph taken, sitting on the table. She wanted another one, and placed the baby in a chair and put a cat in his lap. The cat bolted, and in making a grab at its tail the baby fell with the chair and struck his head on the floor. He was never well afterwards, and died on Sunday last. Dr. George Robert Young deposed that death was due to meningitis, the result of the fall. The gloomy comment of one juror was that there is a saying

that it is unlucky to have a child's photograph taken before it is twelve months' old, and it proved so in this case; but the jury returned a verdict of accidental death.

**A RHYL Mystery.**—Mr. Charles Henry Deakin, photographer, of Newcastle-under-Lyme, whose clothes were found on Rhyl beach a month ago, has returned to his home. It was not believed that he was drowned, as he was stated to have been seen in Liverpool subsequent to the discovery of his clothes. Any explanation of Mr. Deakin's strange disappearance is refused at his residence.

## SYSTEMATIC TONING OF P.O.P. POST-CARDS.

the advent of the postcard came the necessity for considerable re-adjustment in the routine of the printing-room, if the photographer would successfully meet the increased demand of his output. Studios in small towns that had become accustomed to a weekly output of some dozens of silver prints, principally portraits, were confronted with the problem of producing grosses where dozens had hitherto sufficed. Not only the photographer to deal with increased quantity, of which a sufficient cause of embarrassment to men with limited means and appliances, but as there was no corresponding monetary increase, owing to the reduced price of the postcard, became necessary to avoid any increase in the way of standing expenses. The printer who handled dozens must be prepared to handle grosses, and in the same or even less time; moreover, the margin for waste was of the narrowest, his methods must give certainty of result. The following account of my method of dealing with postcard work may be of interest, and possibly of use, to those photographers who, without being able to retain a large staff of workers, yet require to produce the grosses weekly, and who require a technically good card with a minimum of labour and expense.

### Working from Reproduced Negatives.

It is my practice to use only reproduced negatives for postcard printing, the negatives being made from carbon transparencies obtained from the original 9 by 7 negatives. By using reproduced negatives, I am able to get an average of uniform density that greatly facilitates printing operations. So far from the negatives being kept thin, they are of good density, such as would give a bright print with albumen paper; thin, ghostly negatives are extremely productive of waste, to say nothing of the difficulty of getting good tones, especially with the toning bath I am about to describe.

### Printing by Test Negative.

The negatives are classified according to density, and lettered A, B, C, or D, as the case may be, such classification being, of course, entirely arbitrary. Four postcard negatives in a convenient number to handle in each frame, and the frames are filled from the classified densities, a letter corresponding with the negative density being temporarily affixed to the outside of the frame to prevent error. One negative of each of the densities printed from is retained for use in a small frame as a test or actinometer print. The frames being charged, they are put out to print in groups, each group having its proper test negative. Of course, it is only necessary to examine the tint in the small frame; when that is done all the frames corresponding to the density indicated by it are taken in and changed. On overcast days of fairly uniform light the first printing may be timed, and by doing so a fairly close guide is obtained to the time required for subsequent batches. Hence the printer may be relieved from constant attendance on his frames, and able to progress with washing and toning operations. From practical experience, I find that two gross of postcards is a very convenient batch for one printer and toner to handle. Of course, with an assistant and division of labour the size of batch may be greatly extended. Having thoroughly freed the cards from the free silver by washing and soaking, they are ready for toning.

### Avoid Sulphocyanide.

Now, it is open to question whether the sulphocyanide bath is largely advocated for toning gelatine papers is the ideal bath its extensive employment would suggest its being. Without doubt, in the early days of gelatine papers few of them would tone satisfactorily with any other bath, and at the

present time I know of several commercial papers that are only amenable to sulphocyanide. Generally speaking, the best commercial papers can be toned quite as well by other baths as by sulphocyanide; in fact, the makers in some instances give a choice of other baths. For toning large batches I do not hesitate to deprecate the use of sulphocyanide; it may be that some emulsions and some workers succeed admirably with it, but, judging by the experiences of a good many workers, I know that it is capable of causing very disastrous results when least expected. (*Par parenthèse*, a word of history with regard to the sulphocyanide toning bath may not be without interest; its use is so inseparably associated with the advent of gelatine emulsion papers that one gets to regard it as having been specially introduced as a toning agent for them, whereas it was in use in exactly the form recommended by several manufacturers of the present day at least thirty-five years ago, as a toning agent for albumenised paper.)

### The Toning Formula.

The toning bath I have used for the last two years when dealing with considerable batches of postcards is an acetate bath on the lines of those so extensively used in the days of albumenised paper printing; and, although I have toned some thousands of cards with it, and cards from various makers, I have not yet known an unsatisfactory batch as regards colour. In working, it far surpasses sulphocyanide for regularity, and it has the great advantage of keeping indefinitely as a stock solution. The stock solution is made up according to the following formula:—

Sodium acetate .....	16 ounces.
Gold trichloride .....	240 grains.
Distilled water .....	60 ounces.

The chloride of gold is first neutralised with chalk, and the stock solution requires at least twenty-four hours ripening before being used to prepare the toning bath.

The toning bath proper is made up according to the quantity of postcards to be toned. I find sixteen grains of gold ample for toning two gross of prints. The stock solution is used in the proportion of two drachms to ten ounces of water, or one and a half ounces of stock solution to sixty ounces of water, which forms the quantity used for two gross of postcards, additional gold from the stock solution being added from time to time as the gold gets used up, until about sixteen grains have been used for the two gross.

Let me state here, to prevent any possibility of disappointment, that I do not advise anyone desiring purple tones to try and obtain them with the acetate bath unless their negatives are very much denser than is desirable for expeditious printing. The acetate bath is the bath for rich brown tones, and such it gives readily with negatives of moderate density. Purple tones would, of course, require considerably more gold than is given above for the two gross.

### Toning the Cards.

The sixty ounces of toning bath is contained in a dish about eighteen by fourteen inches, and some two and a half dozen cards, carefully drained from the last washing water, immersed one at a time. After rapidly turning these over once or twice, they should be placed to one side of the dish, and a second like quantity immersed in the toning bath, being kept by themselves. By the time these have been turned over the first batch will be ready to leave the toning bath, and they may be lifted out *en bloc*, and placed in a large vessel of water, with quick separation. Toning with gelatine emulsion is very much quicker than with albumen, and care must be

taken not to tone beyond a reddish brown stage, which is reached well under five minutes. By keeping five dozen cards in the bath at one time, toning is soon accomplished, and after washing in one change of water, the cards may be fixed.

#### Precautions in Fixing.

Two fixing baths are made up, one of 6 per cent. hypo, the other of 4 per cent., the cards being placed in the 6 per cent. bath for ten minutes, and then in the weaker fixing bath for a further ten minutes. In transferring the cards from the washing water to the first fixing bath, each card should be drained of the adherent surplus water by holding it diagonally, otherwise the fixing bath will be weakened by a considerable amount of additional water. About half a gross of cards should be placed in the bath and kept constantly turned for the ten minutes, then transferred to the second bath, and operated by an assistant. Thorough fixation has so often been insisted upon in these pages that it seems superfluous to draw attention to it again, but I fear many photographers still regard fixing as an operation unworthy of their serious attention, and one upon which no time need be "wasted." The practice of getting the prints into the fixing bath and then leaving them to take care of themselves for ten or fifteen minutes cannot by the most charitable be called "fixing," and should never be tolerated by anyone who aspires to even a moderate amount of permanence for his work. Years ago I convinced myself by actual experiment that carefully fixed prints might have an appreciable amount of hypo left in them, and yet be more permanent than prints carelessly fixed and subjected to the absurd amount of washing most photographers seem to think essential to permanence.

#### A Practical Washing Procedure.

With regard to the washing of postcards, I am afraid that my method will scarcely commend itself to the majority of workers. However, as it possesses the twin merits of expedition and efficiency, I will include a description, without any hope that where the careful work of MM. Lumière has failed to convince my description will carry much weight.

For the two gross of postcards two large trays, each capable of holding about half a gallon of water, are taken. The prints are removed, one at a time, from the fixing bath and carefully drained before being placed in the washing water. I attach

great importance to careful draining of each card as it enters the fixing bath, as I find by actual measurement that the prints are rapidly taken from the fixing bath and pass into the washing water, the two gross of postcards taken into the first washing water *fifteen ounces of the fixing water* so that if this rapid passing of cards from one bath to the other is kept up, an enormous amount of washing is required to get rid of the surface hypo. My method of washing, is to pass the cards with careful draining from one tray to another for about four changes of water; the cards are left soaking for about ten minutes, after which the water is poured off, the cards being evenly distributed over the surface of the dish while pouring away the water, and then a squeegee used over the whole, with firm pressure in one direction, so as to press out as much fluid as possible. The tray is again filled with water, the cards left to soak, then washed from tray to tray, as previously described, for another four waters, squeegeed again, washed again with water, squeegeed finally, and placed to dry. I find by actual method that the last washing water shows "no hypo" as tested by the usual means. The Editor of this paper recently pointed out that even after the surfaces of a postcard are freed from hypo the body of the card may contain quite an appreciable amount, and the object of the squeegeeing is to get rid of this deep-seated hypo.

I am afraid anyone reading this description will not accept this method of washing as being expeditious; however, so in fact it is. Two gross of postcards can quite easily be washed in three-quarters of an hour, single handed, by the above method. Washing prints by throwing them into trays, and letting them remain under a tap for so many hours is slow and incompetent; with postcards, owing to the water-logged condition they so readily assume, it is downright absurd. One or two boys can easily be trained to wash the cards thoroughly and quickly, and they are out of hand at the end of the day's work, instead of getting sodden by soaking all night.

Such, then, is the system I adopt for dealing with small batches of postcards, and although it will scarcely commend itself to the extensive producer of P.O.P. cards, it is, as suggested at the commencement, a very convenient method where only a few gross weekly are wanted.

G. T. HARRIS, F.R.P.S.

## ON THE PHOTOGRAPHY OF THE INFRA-RED RAYS

(A Note Presented to the Paris Academy of Sciences.)

In 1880 Sir W. Abney published\* the announcement that, under special conditions, a collodio-bromide emulsion exhibited a remarkable sensitiveness to the less refrangible rays of the spectrum. Abney distilled off the ether, washed, and redissolved the pellicle. He believed to have reached wave-length  $2\mu$  in the solar spectrum, but the limit was actually  $1.4\mu$ .<sup>\*</sup> Nevertheless, the process exceeds in photography of the infra-red the use of any of the sensitising dyes. It has been reattempted since, but never, it would appear, with any success. I have established the condition of production and the nature of the product in such a way as to enable me to eliminate the causes of the failures of my predecessors. I have devised certain new processes which give results superior to those of Abney, and which are, I hope, susceptible of still further improvement.

\* Phil. Trans., CLXXI. 1880. CLXXVI. 1881.

† Rubens (Rapports présentés au Congrès de Physique, t. II., p. 144. Paris, 1900) has given the limit as  $1.4\mu$ .

1. I first raised in different ways the proportions directed by Abney. In all cases, under the influence of heat, the sensitiveness of the emulsion to the less refrangible rays was found to be considerably increased both when silver or bromide was in excess. The transformation, however, is sharper with silver in excess, and takes place partially even in the cold, if the excess is considerable—e.g., 1 gm. to 5 gms. silver bromide.

An emulsion obtained by means of concentrated solutions of silver nitrate and bromide of zinc or cadmium became more sensitive than emulsions prepared in the ordinary way.

The reduction of the pyroxylin, which was carried as far as possible, was also favourable to sensitiveness.

It should be noted, as one of the principal causes of failure, that it was not always possible to reach, even approximately, the number given by Abney without the bromide precipitating in large flocks. According to its mode of preparation the pyroxylin confers on the mixture of ether and alcohol a different

viscosity—varying from 1 to 10, according to some writers—and is this which determines the quantity of silver bromide which can remain in suspension. I have had to employ 1.5 gms. of pyroxylin (feebly nitrated) for 10 gms. of silver bromide—that is, ten times the quantity given by Abney. The emulsion described by Abney may be characterised as follows:—Greatest possible concentration of the reacting solutions; permissible minimum of pyroxylin to give a homogeneous emulsion.

The bromides of zinc and ammonium are almost exactly equivalents. The mixture of alcohol and ether can be replaced by ethyl-alcohol or acetone. The transformation of the silver bromide is then of a purely physical order, and is also always accompanied with an increase in the size of the grains.

Lastly, the emulsion was exposed under pressure to temperatures rising up to 100 deg. F. during one hour, and 40 deg. during twenty-four hours. It was not found possible to exceed the limit named by Abney, the bromide becoming granular and decomposing.

It is well, after distilling off the ether, to allow to cool, to re-add the ether, to shake, and to commence the operation afresh. Solutions two or three times as dilute as those directed by Abney can thus be used, and a more homogeneous emulsion thus prepared.

The sensitiveness to white light is also increased, but not in the same proportion.

2. It is well known that when exposed to heat a gelatinous emulsion increases enormously in sensitiveness to the more refrangible rays, less for the yellow and red, the variations of the concentration of the salts and of the gelatine having the same influence, *mutatis mutandis*, as in Abney's emulsion. This similarly led me to suppose that the same phenomenon characteristic of silver bromide is manifested in each case, and the following experiment was undertaken to confirm this view. A precipitate of silver bromide was obtained under suitable conditions in alcohol, or water, washed, and heated for a few minutes in water, either pure (which is best) or with the addition of a little silver nitrate. It gave, after emulsification in gelatine and fresh application of heat, plates which are much more highly sensitive to the infra-red than those of Abney. After five minutes' exposure to the spectrum of a Nernst lamp, far poorer in calorific rays than the solar spectrum, which was used by Abney, we obtained an impression which decreased steadily from the blue to 1.4 $\mu$  without showing the abrupt breaks as do plates containing colouring matters. The characteristic blue colour of the Abney emulsion (evenly transmitted light) appears immediately, and in the cold. I shall give the technical data later.

WALTER RITZ.

## FOREIGN NOTES AND NEWS.

### The Alum Fixing Bath.

The following abstract of a paper, recently read by MM. A. and L. Lumière and Seyewetz, before the Société Française, will be useful, setting at rest the moot point as to the value of the alum and hypo fixing bath, the use of which has been strongly deprecated in some quarters. The use of sulphite to prevent the decomposition of the alum and hypo was first suggested by Valenta in 1889. The use of sodium bisulphite, or acid sulphite and soda, is, however, new, we believe, though as this compound may be formed by the addition of sulphuric acid to sodium sulphite, it will at once be obvious that the chrome alum, sulphite and sulphuric acid and hypo fixing bath suggested first by Cramer is indirectly the bath now suggested. The authors point out that it is well known that more or less complete insolubilisation of a gelatine film may be effected by the addition of formaline, formosulphite, or alums to the fixing bath. The disadvantages of formaline are that it leads to subsequent stripping of the film and considerable discolouration of the fixing bath if any traces of developer are carried into the bath.

Alums slowly decompose the hypo, giving rise to the deposition of sulphur and subsequent sulphurisation of the images.

The bisulphites of aluminium or chromium in suitable proportions in the fixing bath will render gelatine insoluble, without giving rise to the precipitation of sulphur. The same results can be obtained by admixtures of an alkaline bisulphite and ordinary or chrome alum.

Comparing the action of the two alums it was found that using a 15 per cent. solution of hypo the greatest insolubilisation of the gelatine was produced with 0.5 per cent. of chrome alum and 1.5 per cent. of ordinary alum. Chrome alum is much superior to ordinary alum, as one-third of the quantity is required, and, further, the gelatine is so hardened that it will stand a temperature of 212 deg. Fahr. whilst with ordinary alum at 167 deg. Fahr. the gelatine softens and strips from the glass.

The quantity of sodium bisulphite and the commercial solution referred to, should not exceed 1 to 1.5 per cent. Less than this quantity produces incomplete insolubilisation and with excess, the hardening action is quite destroyed.

Testing the plates thus hardened, the authors find that the hypo is eliminated as rapidly as if the film was not hardened. Intensification and reduction also take place as rapidly as with plates fixed in an ordinary fixing bath.

As the gelatine will stand such high temperatures without softening hot water may be used for elimination of the hypo, with consequent

hastening of the operation. Further, the negatives may be rapidly dried by heat without any melting or running of the film.

The actual formula there for a fixing bath made up on the above experiments would be:—

Hypo .....	3 ozs.
Sodium bisulphite lye .....	100-150 grs.
Chrome alum .....	50 grs.
Water .....	20 ozs.

The hypo should be dissolved in the greater part of the water, the bisulphite and chrome alum in the remainder, and the solutions mixed.

### A New Yellow Screen Dye.

Dr. Franz Novak calls attention in the "Photographische Korrespondenz" to a new dye, called "filter yellow K," which has been introduced by Meister Lucius and Bruning. The special feature of this new dye is that it absorbs the whole of the ultra-violet, a feature which is possessed by very few of the yellow dyes now used for making

colour screens. The accompanying diagram is from a negative taken in a large quartz spectrograph of the K. K. Lehr und Versuchsamt at Vienna, and it will be seen that the absorption extends from L in the ultra-violet to 6 $\frac{1}{2}$  F.

### Alum in the Combined Bath.

The composition of the combined bath has always been one of those questions upon which the theorist has too often been at variance with the practical worker, for it has been a fact established for many years now by the researches of Valenta, of MM. Lumière, and Chicandard and Seyewetz, that alum or an acid, when mixed with hypo, gives rise to the continuous evolution of sulphurous acid, sulphuretted hydrogen, and the precipitation of sulphur with the absolute certainty of sulphurisation of the silver image.

The practical worker has proved that combined baths containing alum not only gives better tones and greater regularity, but the prints thus treated have stood for years without showing any change. The advantage of the use of alum, too, in hot weather is obvious.

MM. Lumière and Seyewetz have examined this question again, and

point out that the tanning action of combined baths containing alum is practically nil, if the baths are made with boiling water, as is usually recommended, because nearly the whole of the alumina is precipitated. Probably as the natural corollary of their researches mentioned above, they now find that the commercial solution of sodium bisulphite entirely prevents any decomposition of the hypo in the combined bath by alum, and suggest the following formula:—

Hypo .....	5 ozs.
Sodium bisulphite lye .....	100 minims.
Lead acetate .....	20 grains.
Alum .....	400 grains.
Gold chloride .....	6 grs.
Water .....	20 ozs.

The authors find that ordinary alum is superior to chrome alum; paper treated with the above bath tones very little slower than with the ordinary bath, blisters are entirely avoided, and the gelatine will stand a temperature of 176 dg. Fahr. without melting.

### Testing Old Toning Baths.

Karl Worel, of Graz, calls attention to a very simple method of testing old toning baths for gold and platinum, which may possibly be

useful. It has been worked out by Donau at the technical High School at Graz. A small loop is made at the end of a short length of platinum wire and heated to redness in a spirit flame, and then dipped in pure borax powder; some of the borax will adhere, and if the wire is heated in the spirit flame it will melt and form the well-known bead. If the bead be touched with an old toning bath containing gold, and again heated a rich ruby red, colour will be imparted to the bead, and so sensitive is this test that it will prove the presence of 0.000025 mg. of gold. Platinum gives a fawn colour by transmitted light, and the bead when looked at is milky, and 0.00005 mg. of platinum can be detected in this way. Alkalies have no effect on the reaction, and only very large quantities of salt cause the colouration to turn violet. Acetates, sulphocyanides, hyposulphites, and phosphates are also without action, and it is only very large quantities of silver that prove troublesome, and this should be precipitated first. The bead must not be heated too long after touching it with the solutions, otherwise the red gold colouration turns blue, then greenish-blue, and then colourless. If large quantities of gold are present and the bead is heated for some time it becomes liver colour by reflected, and blue by transmitted light.

## COLOUR-PRINTING IN ENGLAND AND ABROAD.

### A REPLY TO MR. TILNEY.

MR. TILNEY is always readable, but I am afraid he has allowed fairness to be sacrificed to liveliness in his article on the colour prints at Earl's Court. While, of course, it is well to realise our own shortcomings, I do not think his wholesale castigation of the native engraver entirely deserved, as from my own observation I feel sure the Continental work does not surpass, or even equal, our own efforts, if *speed of delivery* is considered together with quality.

If Mr. Tilney implies that no English engraving work goes abroad he is not quite right, for this has gone over to France. One English firm has a branch in Paris, two others have an agency there, and do a considerable amount of business, while another firm is about to open an establishment for making colour blocks in Paris. It is true that this is not Germany; but all that Mr. Tilney says has been said many times before about France. The colour department of two of the largest colour firms—one in Germany, and the other in Austria—are managed by men whose experience has been largely gained in English or American works respectively.

It is quite true that competent art direction is desirable in photo-engraving, but my experience is that artists generally expressly dissociate themselves from anything connected with photography, to say nothing of photo-mechanical work, which possesses no interest to them except as a target for abuse.

Moreover, I do not think it is art directorships that enable the Continental firms to turn out satisfactory colour work; it is due to the longer time they can spend patiently fine-etching, a time which owing to the speed at which we work in England, cannot be afforded. This rush certainly tends to deteriorate the appreciation of fine work, and lessens finally, perhaps, the capacity to execute it. However, the customer is quite as much to blame as the engraver for this. I have been over the works of three of the four firms mentioned by Mr. Tilney, and if the finished work was excellent, the first colour proofs were quite as bad as I have seen anywhere. To correct these plates does not require so much an artist as a craftsman, who can appreciate a colour match (like a woman always can, without being in any sense an artist) and who knows his materials thoroughly, so that he can accurately imitate the copy before him. The artist, I fancy, would be apt to prefer pleasing colour, even if not quite like the original, or even to suggest improvements; in fact, it is difficult to imagine anyone of real artistic power remaining a copyist, or even a supervisor of the copying of the mass of rubbishy originals at present reproduced in three-colour.

Mr. Tilney is right in recognising the merit of showing original and reproduction together; but he is in error in supposing that English firms shrink from this ordeal. If he had been to the recent Printing and Stationery Trades' Exhibition, at the Agricultural Hall, where the best English three-colour firms were exhibiting, he would have seen numerous exhibits of original and reproduction side

by side, as was the case at the former exhibition two years ago and also at the exhibition at South Kensington.

I take exception, too, to Mr. Tilney's assertion that the original is never delivered with the reproduction. I have been in the trade for many years, and, except by accident, or reasons of inconvenience of size or value, I have never known a reproduction to be sent home without the original, unless by the request of the customer.

Mr. Tilney says that the colour-plates in the "Studio" are printed in Vienna. The blocks are made there, it is true, but the printing is done by a well-known English firm. By the way, if my memory serves me correctly, there was a time when the black-and-white blocks for this publication were made abroad; now they are made in England. It is possible the same thing will happen with colour work. Then Mr. Tilney presumes incorrectly regarding the Unie process being the same as the "nature" grain of Messrs. Dawson, the former makes use of the light-sensitive properties of bitumen, while the latter was a swelled gelatine process. A large English firm bought the Unie process, but, although getting excellent results, has had to discard it, I believe, in favour of quicker methods.

"Four-colour is not worked in this country to any extent, although the examples of it are common enough," says Mr. Tilney, so that apparently the "common enough" fourth colour gets the work without our native engravers knowing it. Surely Mr. Tilney has seen the recent "Vanity Fair" cartoons, which are native typographical colour work not "passing for three-colour."

It is difficult to follow Mr. Tilney, when he first sneers at the efforts to improve the process on the mechanical side (which is what "theory" aims at doing) and at the same time blames the block makers because so much fine-etching is necessary. Does he think that Germans are not experimenting with filters as well as using the "art" direction, because, if so, he is mistaken; though I can assure him they are still doing more fine-etching than we are in England, and, if their results excel, it is due to nothing else but the patient care with which this part of the work is executed. First-class work of any kind cannot be done except at the cost of time; even if journalists would probably improve their matter, without necessarily hurting their playful style, if they took the time to verify their assertions. But our English habit is, unfortunately, not to allow this consideration to weigh when native engraving is concerned; while a customer sending work abroad is willing to wait a sufficient time to give opportunity to have the work done carefully and agree to the number of printings the foreign block maker considers necessary, here the work is generally restricted to three printings and must be delivered in an extremely short time. To an employee, especially a limited company, having no particular interest in the work, except as a means of money-making, this is not unsatisfactory, as the more work turned out in a given time the greater the profit.

Mr. Tilney concludes with fine sarcasm at the expense of the English fine-etcher, referring to the menial duties the apprentice may be called to perform in commencing his career. How, then, does he suppose the German fine-etcher commences his career? Is the capacity of fine-etching fully developed in him before he enters the workshop? Every one may not be capable of becoming a fine-etcher, but the average English fine-etcher of the same experience is just as capable of doing good work as the German, if allowed sufficient time, which would be less than the German would require. I have known a fine-etcher threatened with dismissal unless he could turn out more work, although it was known that with greater speed quality must be sacrificed. I daresay the German has the better temperament for the work of all kinds, including colour reproduction. He is better disciplined, and so quiet that I have seen fifty litho artists at work in a German house and one could hear a pin drop in the room. He is more steady of work than the Englishman, who looks upon his work as a necessary evil, from which he is not sorry to escape in order to partake in some form of sport. This applies to employer as well as to employed, and, carried to excess, is bad. On the other hand,

the nation may be considerably better for this love of exercise; it may explain, for example, why our illegitimacy rate is lower than that of Germany.

Another fact is that the big Continental houses have been making a feature of colour blocks longer than we have; they have, therefore, longer-experienced men, they are generally better equipped as regards apparatus, and especially as regards space. Three-colour in England is rather a recent boom, and at present anyone who can show any sort of pretence at competency is certain of employment. So difficult is it to obtain men that one firm has a standing advertisement offering employment to colour etchers. It is not only necessary to be willing to pay for brains, as Mr. Tilney suggests, there must be a supply available. Unfortunately, fine-etchers have to be made as well as born.

I do not give any names, as it would look like advertising the particular firms mentioned, nor do I wish to blow my own individual trumpet, but I am willing to meet Mr. Tilney if he desires to have further evidence of my statements.

PHOTO-ENGRAVER.

## WORKING-UP PLATINOTYPE PORTRAITS.

The following notes on a special branch of work appear in a recent issue of "Wilson's Magazine," under the name of Miss M. P. Bell, a lady who has written a good deal in the American magazines on the methods of working-up prints.

In these days, when so much of the professional photographer's work is printed in platinotype, it is essential to know how to finish portraits made by this process, for there is no denying the fact that they need to be very carefully worked-up if they are to present a finished appearance possessed by a good silver print from a well-etched negative. Mere spotting is certainly insufficient. There is a roughness in the texture of the image on the platinotype paper that needs pulling together. Careful handling is necessitated by the moisture-absorbing quality of the paper. One must know, too, how much colour to put into one's brush for the effect desired, and a false touch of colour, once put on, cannot be got off again. When once the requisite lightness and firmness of touch has been obtained, however, platinotype paper offers a delightful medium for touch work, and a well-finished platinotype print is (most pleasing to the eye.

The beginner should take up a few waste prints for his early practice. A few black specks may be noticed here and there on the print. These must be lifted out bodily with a knife. A small scalpel or the best knife for this purpose, with its rounded blade and pointed end. Practice in its use will bring skill, and the specks can be easily moved without a mark on the print. Unless they are taken out, they will entirely spoil the effect in the portrait.

When a too heavy touch of colour has been put on, it may be reduced in intensity by quickly applying a brush that has been washed out in clean water. This must be done with scrupulous care, or the surface of the paper, being soft, will rub up, which will be fatal to the print, as it is almost impossible to get it smooth and even again.

The roughness of the paper also necessitates care to see that the colour is so laid on that it appears right whichever way the print is held to the light. It will, of course, look best when the print is viewed in the same light-direction in which the work was done, but the finisher should turn the print round as he works, and view the work from both sides—i.e., lighted from left and right—as the work proceeds.

We will begin with an ordinary vignette photograph that has just come from the mounting-room; but, first of all, let it be dry. Have your colours ready: lampblack and sepia, water, a No. 2 sable brush for the eyes and fine parts of the face, and one or two larger brushes for the broader effects of dress and background. Have also two or three compartments in your palette—a china one—for colour of various thicknesses, or two or three little saucers.

Look at the tone of your print; if it is a black tone, the lampblack by itself will probably match it; but if it is of a warmer tone, slightly inclining to brown, it will be necessary to mix with the black a little sepia. See that the colour, when mixed, is exactly

the tone of the print; I have seen photographs that have been finished with a colour that did not match, and the effect was execrable.

I have always found it well to begin with the eyes, after doing the usual spotting, for spots distract one's attention; the eyes speak out the mind and character of the person plainly, but, because they are so important, they have to be done with the greatest care. Do not try to alter them unless you understand the principles of drawing. Observe where the pupil comes. The pupil and shadows of an eye often come out too faint in a platinotype, and need strengthening; but it must be done lovingly—not to put a black patch of colour in the middle and a black line round with a strong black line for eyelashes, as is so often done in cheap work, but to put the colour in with care and judgment, so as to bring out the beauty of the eye and not make it look like a staring doll's eye. The eyelashes may also be strengthened, but also with care; the eyebrows and any inequalities of lighting can be blended. This is where the pulling together comes in: a strong light here, which catches the eye too much and must be toned down, or a little shading in of the neck there, bringing all into harmony.

The hair, also, often needs attention. In the case of ladies, perhaps the fringe has got an awkward break in it which needs to be filled up, and some shadows may require to be strengthened, or high-lights toned down. Especially is it necessary to touch up the hair in cases where it is turning grey or is quite white. Grey hair always photographs whiter than it is, and people are often sensitive about their hair getting grey, so this must always receive special attention. It must be darkened in all the shadows, and carefully shaded in all the high-lights. I have never known a case yet where this was not necessary.

Having finished the face, you must now take the dress. In white dresses a good deal will be found necessary to do: shadows to be strengthened, and other shadows, perhaps, to put in where detail is wanting. A great deal can be done in this way to improve a photograph and make a pleasing picture, especially in evening dresses, where filmy lace or chiffon seem to compose the bodice. The neck, of course, you have already done.

Now we come to the background, and this is a very important part of the picture. There are two ways in which a background can be put in. One is: have some black chalk and white chalk scraped to a fine powder, also a little sepia chalk to tone the mixture to the colour of the picture, and with a pad of cotton-wool rub the colour into the background, with a circular motion, until the desired tint is obtained. Care must be taken to have no grit in the powder. Now, with a piece of pointed india-rubber, trim off the edges either with a suggestion of leaves or a cloudy effect. There is room for much fancy in this method; it is a quick and ready way of putting in background, and is very effective. The amount of background must, of course, be regulated by the kind of picture it is, and how much is required to throw up the head and shoulders sufficiently in relief.

# PHYSICAL CHARACTERISTICS OF RELIEF ENGRAVINGS, ESPECIALLY RELATING TO HALF-TONES.

THE following is the continuation of the article from the "Inland Printer," by Mr. N. S. Amstutz, the last instalment of which printed last week. The author there referred to certain tables which accompany the present text, considerations of space having compelled their withdrawal at the last moment from last week's JOURNAL. For the same reason one or two of the illustrations referred to in the enclosed text must be held over until the next issue.

TABLE G.—Giving pitches, unit areas and "covering" dots for various lines per inch.

KINDS OF DATA.	Lines per inch for Tables G and H.					
	50	65	85	100	110	120
Screen pitches .....	.02000 in.	.01533 in.	.01176 in.	.01000 in.	.00910 in.	.00833 in.
Diagonal pitches .....	.02850 in.	.02175 in.	.01663 in.	.01413 in.	.01287 in.	.01178 in.
Unit Areas .....	4000.0 sq. in.	2365.4 sq. in.	1380.6 sq. in.	1000.0 sq. in.	828.0 sq. in.	693.9 sq. in.
Diam. of "Covering" dots .....	.02850 in.	.02175 in.	.01663 in.	.01413 in.	.01287 in.	.01178 in.

TABLE H.—Giving percentages, clear spaces and dot data for above listed lines per inch.

\* = CLEAR SPACES OF BLACK DOTS ONLY. CLEAR SPACES OF WHITE DOTS are the same as the dot diameters.

a = Region of "Three-quarter" white, or birth of Crescent dots.

b = Diameters of "Covering" dots.

The illustrated definitions of the names used, shown in Fig. 18, do not show square, diamond or elliptical shaped dots, which are produced by special diaphragms.

The percentages above the "a" region are only approximate. The values are dissipated in "overlapping" and the HIGHEST values indicate the whole area of the overlapping effect, to the extent that they exceed 100.

TABLE I.—Showing relation of clear spaces to depth or printing quality.

b. .01064	889.16	157.	.00000										

\* = Clear spaces of black dots only. White-dot clear spaces are the same as the dot diameters.

a = Region of "Three-quarter" whites, or birth of "Crescent" dots.

b = Diameters of "Covering" dots.

Fig. 20 is based on similar data, but in measured values from Table F.

Figs. 21, 22, 23, are three special test engravings at 65, 110, and 150 lines per inch, in order to determine therefrom the depth values of Table K, at 110 times, the black dot (●) depths, in terms of 1.200 millimeter, at a magnification of .87 diameters, with a series of ten readings gave 15, 14.5, 14, 14, 15, 14.5, 18, 16.5, 17.5, and 14.5, or a mean of 15.35. These are standard etches, and the depth is given as an exemplification of ordinary practice from which to judge the interrelation between various lines per inch, the dots and depths.

It might be said "let well enough alone," but no trial by error process is "well enough," and many failures and anxious moments could be avoided by an intelligent inspection of dot diameters in etching and the use of properly graded stops in the camera. It goes without saying that the degrees Baumé of the acid, as well as its temperature, are vital, and should be noted by the careful etcher.

Messrs. J. A. C. Branfill and William Gamble, of London, have given the relation of stop size and shape to screen distance exhaustive treatment, so that this phase of the subject is only touched on in passing.

It is interesting to note the etching rate of Fig. 2, in comparison with those of Figs. 9, 10, and 11, as disclosed by the curves on Fig. 24, especially the difference in rate between the (o) and (●) dots. This figure, with the gray values omitted, is self-explanatory. Table J gives the data of Table F from which Fig. 24 was drawn, the other data are found in Table A.

MESSRS. HUTCHINSON AND CO. are bringing out a complete natural history, illustrated entirely by the best available photographs. The text will be written in a popular style by such good naturalists as Dr. Lydekker, Dr. Boodle Sharp, and Sir Herbert Maxwell. The first part of "The Living Animals of the World," as the book will be called, has just been issued. There will be twenty-four parts in all, published at 7d. each, and including 1,200 illustrations, with twenty-five coloured plates.

When the white dots (o) are under consideration, the printing quality (14 of Fig. 18) values given in Table I are for ideal conditions. The unit "I" is taken as indicating when the clear space are the same as the depth. This value, if the ink transference from the rollers to the printing face was theoretically perfect, would continue to represent printing quality, even though the dimensions were much reduced below those ordinarily considered as having reached the practical limits of minuteness.

Theoretical printing quality values require a modification, which may be termed the press constant, which will vary with the ink, hygroscopic, temperature, and paper conditions. The values given in Table K show a better printing quality for the white dots than for the black ones (●), because the depth, in proportion to clear space, is greater in the case of the former than the latter; this explains why the white dots (o) will persist in printing in background, etc., when the customer may want a dead black, which cannot, however, be attained in proper harmony without remaking the engraving or burnishing down the size and depth of the undesired dots.

If the printing quality of the white dots (o) was not better than that of the black ones (●) the minuteness of their dimensions would certainly not admit of any printing value at all. When one deals with diameters of .0026 inch and depths of only .0012 inch at the points where the largest masses of ink are dealt with, the results are little short of marvellous, and the engraving and allied printing arts take on all the features of precision engineering.

N. S. AMSTUTZ.

It is announced that Dr. R. A. Reiss has been appointed Extraordinary Professor of Scientific Photography in the University of Lausanne. Another sign of the tendency on the Continent to provide instruction in the principles of photography from the scientific standpoint is the appointment of Dr. W. Scheffer, of the staff of the C. P. Goerz Optical Works, to deliver a course of lectures on applied scientific photography in the Berlin University during the summer season.

## COUPON FRAUDS.

Coupon fraud has been worked recently in the suburbs bordering Epping Forest. The methods adopted are those which have been used in our columns more than once. The alleged agent of a photographer calls at a house and explains that on payment of a small sum a coupon can be had which will entitle the purchaser to sitting at a nominal sum in a studio in the neighbourhood. The coupon represents the canvasser's headquarters as at a distance, and when the purchaser visits the studio in his vicinity he finds that the photographer indignantly denies any knowledge of his self-styled representative, of whom no more is seen. This stereotyped and is constantly reviving, the latest exponent of it being a man who, as a correspondent writes us, was recently prosecuting his business in the Eastern suburbs of London. Our correspondent writes:—

For some time past a man has been calling upon residents in Epping Forest and neighbourhood selling coupons bearing the name of a photographer in Bond Street, W., with whom I am quite acquainted, and stating that firm to have purchased my business, and that they are supplying pictures at ridiculously low prices. In many cases persons have unfortunately believed the story and parted with their money, and they have been told to call at my studio on main Sunday afternoons. My premises are, of course, always closed on Sundays, and when they have called and found this to be the case they have begun to understand that something was wrong. Naturally, such a state of affairs has caused me considerable annoyance, and is damaging to my business, as, of course, I should not think of issuing coupons. The police have had the matter in hand some time, but have not succeeded as yet in catching the party. Enquiries made at the firm whose name appears on the coupon show that such coupons are honoured at that establishment, and that they give books of coupons to any one who likes to ask for them without giving their name and address. I might mention, however, that I wrote twice to the firm in question laying the matter before them and they did not answer my letters, copies of which are in my book. It occurs to me that the man may have made use of photographers' names in other districts in a similar way, and if you would make the matter known among your readers it might lead to a solution of the matter. Of course, the object in making use of a local name is the difficulty he would find in selling coupons for sittings at an establishment ten miles or so away. The man is described as dark, clean-shaven, middle height, dressed in blue serge suit, and having a usual plausible manner.

The "Daily Mail," in a recent issue, gave the following account of the canvassing frauds:—

"Two 'well-dressed and gentlemanly' men appear to have made some progress with a photographic coupon swindle. Calling on people in the suburbs, they present a photograph coupon order for 6s. 6d., purporting to be issued by 'Lintott, photographer, 118, New Bond Street, W.,' with the special inducement that the first thirty coupons will be sold for 3s. There is no 'Lintott, photographer,' at 118, New Bond Street, though, up to six weeks ago, a genuine coupon business was carried on there by a person of the name, who had previously called in his coupons. The ingenious swindlers appear to have copied the coupons, and their success can be measured by the fact that a firm of art dealers at the address given have been called upon by about sixty coupon-holders."

This account is confirmatory of that of our correspondent, and we have have ourselves ascertained that Mr. Lintott, who, until recently, was practising photography at 118, New Bond Street, was unable to renew the lease of his premises, and, on account of this fact and on that of his wife's health, has removed his business to a town on the Riveira. Possibly this fact was known to the present workers of the coupon frauds, who have taken advantage of Mr. Lintott's removal to use his name and address in this swindling business.

MOTHERWELL Young Men's Institute Camera Club. — The fifth annual exhibition of pictorial photographs will be held on November 7, 8, 9, and 10, 1906. Entries close October 25; exhibits, November 2. Prospectus and entry form will be obtainable in a few days from the secretary, Mr. Jas. Dunlop, Myrtlebank, Motherwell, N.B.

## Photo-Mechanical Notes.

## A New Photo-Mechanical Non-Photographic Colour Process.

A TITLE, such as the above, which is perhaps a contradiction of terms, must nevertheless be used to describe the process patented by Max Grünbaum, of 55, Wolfhager Strasse, Cassel, Germany. The complete specification (No. 17,638, 1905) at once disclaims any spectrographic basis of the process.

The picture is not broken up into the three colours by photographic means, but by the preparation of water colour drawings by hand by a chromolithographer having a good eye for colours. Outline proofs are prepared from the picture to be reproduced, and these are coloured by hand in water colours for the blue, red, yellow, and possibly grey plate. These three or four water colour drawings or washes are united upon a plate, as in the figure.

The arrangement of the water colour drawings upon the plate is of greatest importance. It is effected in the following manner: Upon a square plate A B C D lines are drawn through middle point E parallel with the sides of the square and connecting F (the middle of the side C D) with G (the middle of the side A B) and H (the

middle of the side A D) with J (the middle of the side B C). After this the two diagonals A C and B D are drawn. Upon this plate there is then fixed in the panel or division E J C F which has been formed the water colour drawing for the red printing block, in such a manner that its longitudinal axis runs exactly in the direction of the line E J. In the adjacent division H E F D the drawing for the blue printing block is fixed, so that its longitudinal axis runs parallel with the diagonal D E. The drawing for the yellow is arranged in the division A G E H, and if there is a drawing for grey it is arranged in the division E G B J, the two being opposite and their longitudinal axis making an angle of 20 degrees to the line E G. By this means both angles will have the same apex X.

## Line Blocks from Sepia Prints.

A recent patent (No. 2,149, 1906) of W. Graaf and Co., of 10-11, Potsdamerstrasse, Berlin, claims protection for the following process: A print is employed with white lines upon a brown background, in a similar manner as used for the preparation of ordinary positive copies. Such prints are known as sepia prints and by similar names, and they are usually obtained on papers sensitised with mixtures of nitrate of silver, citrate of iron and ammonia, tartaric acid, and gelatine. A print obtained in this manner is put upon a printing plate or a printing stone, which has been previously coated in the well-known manner with a sensitive bichromated gelatine coating, or with a coating of bichromated gum or of asphaltum, and it is then exposed to the light. After the printing process, the printing plate is developed in the well-known manner and made ready for printing.

**PHOTO-MECHANICAL PATENTS.**

The following patent has been applied for:—No. 18,183. Improvements in the production of plates for printing purposes. Sherard Osborn Cowper-Cowles, 4, South Street, Finsbury, London, E.C.

**Exhibitions.****PHOTOGRAPHS BY MR. S. L. COULTHURST AT MANCHESTER.**

On Saturday, September 8, a "one-man show," consisting of the work of Mr. S. L. Coulthurst, was opened at the rooms of the Manchester Amateur Photographic Society, 57, Market Street. The collection of pictures numbers eighty-two, and a special feature of the catalogue is that the date (of the original negative, we presume) is set down against each picture. Thus additional interest is given to the exhibition, inasmuch as it becomes a photo-biographical record of the worker as well as a record of his work.

Having examined each picture, and marked the works that made the strongest appeal to us, it is interesting to note, upon reference to the dates, that four out of eight, belong to the middle of the last decade, two to 1904, and two to 1906.

It is not a collection of Mr. Coulthurst's best work, and of that only. The preface of the catalogue invites us to view the exhibition from a particular view point. "It is intended to be representative of the author's exhibited work covering a period of fourteen years." Naturally, therefore, it contains some prints that Mr. Coulthurst would not exhibit in the ordinary way to-day. It is, however, all the more interesting biographically, and we are persuaded that such an exhibition is more instructive to the members of the M.A.P.S., for whom it is primarily prepared, than it would have been had it contained only such works as the author's present and chastened judgment would approve.

The exhibition is also interesting from the "process" point of view. Here we have represented all the usual printing processes of the period, even Ozobrome, the youngest of a large family, making a welcome appearance. As to subject matter, the show could hardly be more varied. It includes architecture, landscape, seascape, portraiture, figure work, and examples of still life.

One of the earlier pictures, "The Old Bridge," "An Essex Backwater," "An Autumn Sunset," and "When grey-ey'd morning, etc.," please us best. Among the most successful of the later ones may be mentioned "Hoar Frost and Mist" and "Freeze, freeze, etc.," two excellent winter pictures; while "The Children's Corner" is a charming representation of sunlight, white dresses, and child life, harmoniously treated. The exhibition will remain open till October 6.

**Patent News.**

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications have been made for Patents from August 27 to September 1.

**MIDGET APPARATUS.**—No. 19,383. Improvements in apparatus for miniature work. Herbert Bettesworth Page, 111, Hatton Garden, London, E.C.

**COMPLETE SPECIFICATIONS ACCEPTED.**

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PHOTOGRAPHIC DESIGNING.**—No. 7,250. 1906. The invention is a system of designing by aid of photography. The apparatus forms an endless number of pictures different from each other, but all from the same unit design. The base plate, 1 (Fig. 6), rests on a frame, *a*, which carries a reflecting surface, *b*, sloped towards a source of light, *c*. The ground plate, 1, has an opening and receives a frame, 2, which carries the unit design serving

as base for the production of various figures. A plate, carried by four columns, 3, fitted to the base plate, 1. An objective, 5, directed downwards is arranged in the middle of plate, 4, and can be covered over by a flap, 6. A photogra

Fig. 1.

camera, 7, is arranged above the objective and has a back resting on a plate, 8. According to Figs. 1 and 2, the frame is provided with a conically shaped aperture to receive a rim, formed integrally with a disc, 14, and in which aperture the

Fig. 2.

13, is adapted to rotate. This serves as guide for the discs, when turning the same; the turning of the discs being effected by worm gear, 15. In order to have an exact measure for

Fig. 3.

Fig. 5.

turning, the disc, 14, has a scale provided on a ring, 16, over which a pointer, 17, fastened on the frame, 2, engages. The central opening, 13, of the plate, 14, is for the most part covered by a disc or mask, 19, firmly screwed on to the plate, 14, by means of four screws, two of which are shown in Fig. 2. O

the mask, 19, the transparent plate, 21, is arranged and kept tight by spring controlled arms, 22, these arms being secured to the disc, 14. When the crank handle, Fig. 1, is rotated, all the parts, 13, 14, 19, 21, and 22 and aperture, 20, rotate together, and therefore during the whole rotation the same portion of the ground figure remains always over the aperture, 20. The disc or mask, 19, has a recess or opening, 20, with a central angle of 45 degrees, whilst the scale, 16, shows sixteen equal divisions. The opening, 20, is covered by the photographic negative, 21, which carries the unit design and is held to its support as described by clamps, 22. Four pins, 23, serve for fixing the frame, 2, to the base plate, 1. With the arrangement shown in Figs. 1 and 2, the photographic plate, 21, on which a unit design of any kind has been applied by hand, by means of a relief copying apparatus or a Rose-engine or the like is laid

Fig. 4.

on the mask, 19, so that that part of the unit design which has to be utilised for the production of the pattern is situated above the opening, 20, and is then fastened in the manner described. Then the whole arrangement is placed on the base plate, 1, and is sealed from above against the light in the manner shown in Fig. 6, whilst the light coming from the source of light, *c*, can enter through the above-mentioned opening of said plate. The part of the unit design situated above the slot, 20, is then photographed, and afterwards the objective is covered over the flap or cover, 6, and the disc, 14, turned through a certain

Fig. 6.

angle. In the present case this is taken corresponding to the central angle of the slot, 20,  $\frac{360}{8}$ , viz., 45 degrees. The corresponding part of the unit design is now again photographed, so that, in addition, the picture already existing on the plate in the back, 9, the same picture is directly photographed beside it. In this manner eight pictures are formed consecutively on this plate. As these, however, taken together do not in this special case form any figure complete in itself, they are formed on a second plate in a similar manner. Both the plates are then developed and so placed with their picture sides together, that the part pictures of the one plate fit as mirror picture to that of the other plate, and so form a rosette-shaped figure, and then both the plates are again photographed together. The pattern shown in part in Fig. 7 is an example prepared in this manner. Instead of

two unit designs of the same kind, the unit designs of different kinds prepared in this manner may be combined to form a picture. An endless number of various patterns may be formed from one and the same unit design, according as one or other part of the same is placed over the slot, 20, and according as this slot or its central angle is larger or smaller. According to the displacement the partial figures may be more or less interwoven, or may be arranged at definite distances from each other. For example, each separate part of the scale may be skipped over when exposing. From the first pattern produced from the unit design, according to the same process, the most numerous variations can be obtained, as is shown by holding any desired part

Fig. 7.

of Fig. 7 between two flat mirrors, standing vertical to the plane of the picture and arranged at an angle to each other. Besides, however, pictures obtained in this manner, as has already been referred to, others may be obtained by interweaving the same. In order to obtain a completely uniform picture, the above-mentioned angle, which is represented by the amount of displacement must naturally be a perfect fractional part of 360 degrees, but within these limits may be as large as desired. The scale, 16, might also be otherwise added up. The same applies for the slot, 20. Either a separate mask, 19, may be used for each slot, 20, or several slots may be arranged in the same mask. Neu Graphic Actien Gesellschaft, Orlikon, Switzerland.

PLATE CHANGING.—No. 23,431. 1906. The apparatus requires the 21 figures for its explanation. William Augustus Peters, Johns town, Pennsylvania, U.S.A.

#### CATALOGUES AND TRADE NOTICES.

A profusely illustrated circular of backgrounds reaches us from Messrs. Turner and Co., of Exchange Street, Blackburn, who make a special line of these and other studio accessories such that it should be worth any photographer's while to obtain the list and examine the very excellent selection of designs offered by Messrs. Turner.

MESSRS. THOMAS ILLINGWORTH AND Co., of Willesden Junction, London, N.W., announce that their new gaslight paper "Zigas" will be ready for the market on October 1, on which date particulars of a £50 competition will be available, and free samples of the new companion to the well-known "Zigo" may be had.

A NEW list of their photographic materials reaches us from the Leto Photo-Materials Company (1905), Ltd., 9, Rangoon Street, London, E.C., in which the sizes and varieties of the various papers are conveniently tabulated. We think the company does their "Leto-Gaslight" paper an injustice by omitting any mention of its particularly pleasing surface, a characteristic of the paper which certainly distinguishes it from others of the same description, and which we know to be appreciated by many, no less than by ourselves, for its rich appearance. The list is sent free on application.

MESSRS. BARTONS, mount specialists, of 114, Golden Hillock Road, Birmingham, send us samples of mounting papers in great variety of colour and surface. We can heartily commend the series of greys, blues, greens, buffs, and browns, as well as some papers with a figured surface. The exhibitions and the work of the better photographers both set the tasteful worker on the quest of papers suitable for mounts and folders, and to such of our readers as have failed to

find all they desire, Messrs. Barton's selection of samples (6d. post free, and worth the money) ought to set at rest all further anxiety. We hope to see good use made of the papers by both professional and amateur readers.

## New Books.

"Colour-correct Photography." By T. Thorne Baker, F.C.S., F.R.P.S. London: Dawbarn and Ward, Limited. 1s.

"Color" is the spelling adopted in the title and the text, but our friends of Farringdon Avenue will perhaps forgive our old-fashioned preference for the spelling, which represents a more euphonious word, and which is, we believe, philologically less open to objection than that which obliterates our derivation of the word from the French—not from the Latin. But, to refrain from cavilling at orthographical mannerisms, there is surely no doubt of the need of such a book as that before us, and Mr. Baker may be congratulated on presenting a highly technical subject in a simple, almost a colloquial, manner. He who purchases the book in anticipation of an orgy of spectrum curves and absorption diagrams is doomed to the disappointment of not finding one in the book, but the volume is certainly what it claims to be, an exposition of the use of orthochromatic plates and filters in the various branches of indoor and outdoor photography. There are, of course, several points on which we think the author, even though writing on popular lines, might have been a little more precise and correct. For instance, to state that all the colour-sensitive plates are "green"-sensitive is not strictly true, for almost every commercial colour-sensitive plate has the familiar gap in the green, and is really yellow-green sensitive. Again, we are told that the "Geka" Flexoid filters are made of celluloid, whereas the base is gelatine. Want of precision in formulæ and working details is particularly noticeable in the instructions for making the liquid for a tank dark-room lamp, and in the preparation of the filters. Taking the former case, the author prescribes certain quantities of dyes and "water—a sufficient quantity to cause any deep ruby rays to penetrate"; exactly how much this may be could only be told by spectroscopic examination. Again, for preparing the yellow screen, we are told to stain fixed-out lantern plates till they "appear of a light lemon-yellow colour," directions which, considering the many accurate formulæ extant for making screens of definite absorption, are rather loose. Stress, too, is laid on the absorption of the ultra-violet, and, in a list of "anilin" dyes, as the author calls them, naphthol yellow, tartrazine, and aurantia are specially recommended for absorption of the same; whilst, unfortunately, they all transmit a distinct and strong band in the ultra-violet. The statement, too, that the mixture of Canada balsam and xylol, recommended for cementing the screens, will dry in an hour, is certainly not true. One of the chief defects in the work, however, is the omission of all mention of the development of panchromatic and colour-sensitive plates by time alone, the method which is practically the only satisfactory one. The book is issued by Messrs. Dawbarn and Ward in style uniform with the comprehensive "Figures, Facts, and Formulæ," and other recent handbooks on photographic work.

Our contemporary, the "Deutsche Photographen Zeitung," over which Herr K. Schwier presides, sends us the catalogue of the exhibition at present being held at Breslau in connection with the Convention of the Deutscher Photographen-Verein. This body, composed almost exclusively of professional photographers, meets this year in the Eastern Province of the German Empire, and the exhibition brought together in consequence of its visit embraces prints submitted in competition for prizes offered in considerable number by the houses in the German photographic trade. The catalogue, which is issued at sixpence, contains sixteen supplements in photogravure, and other photo-mechanical processes, among which is an exquisite and characteristic piece of portraiture by Herr R. Dührkoop.

We have to welcome the seventy-sixth number of "The Photo-Miniature" (Dawbarn and Ward, 6d.), the chief contents of which are chapters on the hand camera. The treatment of the subject is on modern lines, as evidenced by the special chapter dealing, in a practical way, with orthochromatic photography with a hand camera. The formulæ for sensitising plates and making light filters, though not advanced as new, should, nevertheless, be perused with interest on account of the success which has attended their use in practice.

## New Apparatus, &c.

The "Soho" Repeating-Back. Sold by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.C.

A very convenient back for midget photography has been introduced by Messrs. Marion, under this title. Its construction and mode of use will be explained by the drawing without many words of explanation. The dark slide to which a focussing screen is attached has its two way movement (across, and up and down the plate) supported by the movement of the slide in its horizontal guides either direction. As a result, the manipulation of the apparatus exacts very little from the operator in the way of attention at focussing—the figure shows the apparatus at this stage. The slide carrier is pushed down to the stops EE, and the camera is then ready for the first exposure when the shutter is withdrawn.

slide is then drawn to the left, exposing the lower half of the quarter plate contained in it in three stages, which are duly registered on the dial. The slide is then reversed in position and the (previous) upper part of the plate similarly exposed. The mechanism of the attachment appears to us to be commendably free from complication in its working parts, and the apparatus should certainly prove reliable in practice. The back can be fitted to any half-plate, or whole-plate camera, and costs, including fitting, £3 5s. Extra dark slides are supplied at 10s. We understand that a half-plate size of the back is in preparation.

A NEW FORM of lens mount has been designed by Mr. J. E. Goold, the official photographer of the well-known engineering Tynes firm of Armstrong. The essence of the invention lies in the form given to the mount, which is spherical externally instead of cylindrical. The interior of the mount is, of course, tubular, and the glasses are mounted therein in the usual way. The advantage of the exterior shape is that the mount can be carried in a spherical bearing, and is thus capable of being pointed up and down and right and left in the simplest way, and of being clamped rigidly in any position. The movement thus provides the facilities of a swing from without the bulk and disabilities of camera construction, which that accessory involves. Mr. Goold has also adapted his invention so that an ordinary lens may be attached to the (supplementary) spherical mount, and though this device has not the virtues of compactness possessed by the spherical lens mount proper, yet it has obvious advantages for providing a wide range of movement of the lens.

THE Northern Tasmanian Camera Club will hold an exhibition, in February next, with the following open classes, in addition to those for its members only: Landscape, seascape, portraits, architecture, animals, hand camera work, still life, enlargements, stereoscopic lantern slides, photographic postcards, club exhibits, and colour photography. The secretary of the exhibition, from whom all particulars are obtainable, is F. Styant Browne, 112, Brisbane Street, Launceston, Tasmania.

## New Materials.

"Allochrome" and "Panchromatic" Plates. Made by Wratten and Wainwright, Croydon.

We have received for trial, samples of Messrs. Wratten and Wainwright's "Panchromatic" and new "Allochrome" plates. The latter are much the same as formerly, except for the greatly enhanced sensitiveness. It is frankly stated to be a plate of the usual cyanotype type, sensitive to green and yellow, but not to red, so that light can be used in the dark room; but the effect of the dye is to be much more marked in these plates than in any others we have tried of the same character. As a result, the use of a blue filter does not entail such an increase of exposure as has hitherto been necessary. The same yellow filter, which, on the usual iso plate requires from six to ten times the exposure necessary without screen, on these plates will only require twice the exposure. Consequently, we have been able to take very satisfactory snapshots under any of the conditions of hand-camera usage; with a blue filter in position, and therefore a very much better rendering of the tones of the subjects photographed.

The "Panchromatic" plate is a more remarkable plate, for this appears by spectroscopic tests to be almost equally sensitive to all the visible colours; even the infra red can be photographed if sufficient exposure is given. Of course, the sensitiveness to blue predominates, but to nothing like the same extent as in any other plate we have ever handled. The qualities mean that a very much lighter colour can be used to get a true record in monochrome of any subject presented to the camera when the plate is used. Messrs. Wratten supply a yellow filter to be used for average landscape work, which requires only one and half times the exposure necessary without any filter, and they state that absolute luminosity value can be rendered even the deepest paintings by using their 8-times filter. In our own tests we have been perfectly satisfied with the rendering given by yellow filter multiplying the exposure by four times; and it seemed that any deeper filter would only prolong the exposure without noticeably improving the result.

It is for three-colour work that these plates are of the utmost value. It may be stated that they are being used every day for this purpose in the studio for three-colour portraiture, the three exposures totalling less than five seconds, although the lens aperture used is by no means abnormally large. We, ourselves, tried a three-colour portrait outdoors, but our first attempt was hopelessly over-exposed, and not having a shutter to the lens (working at  $f/7$ ) we had to stop down in order to enable us to give hand exposures of half second through each filter, and yet not over-expose the plate. For curiosity we tried the difference of exposure required under a red filter with these plates, and with the best red-sensitive plate hitherto available, and found that the "Wratten Panchromatic" required exactly one-tenth of the exposure necessary to give the same result on the other plate; and, indeed, we have seen some satisfactory snapshots taken under a red filter.

Owing to this extreme colour sensitiveness we have had to develop these plates in absolute darkness, but using a dark room clock we have had no difficulty in this, and the plates have then been entirely free from fog, giving excellent density and gradation, and, like all Messrs. Wratten's plates, about as near mechanical perfection as could appear to be possible.

Taking all their qualities into consideration, the price, viz., 1s. 6d. for the "Allochrome" and 2s. for the "Panchromatic," per dozen, quarter-plates, is probably justified.

After our experience, we do not think that Messrs. Wratten at all exaggerate in their claims regarding the colour sensitiveness of their new plates, and we feel that their introduction marks a decided advance in plate manufacture.

Kodak Solio P.O.P. (Hardened Film). Sold by Kodak, Limited, Clerkenwell Road, London, E.C.

If a brand of paper which lightens the printers' troubles by ensuring the persistence of a sudden heat-wave is to be deemed a boon, then the gratitude of users of gelatine printing-papers is due to the Kodak Co. for the introduction of a variety of the well-known Solio P.O.P., which possesses resistant properties towards trying weather conditions. In making a P.O.P., no maker

can convert gelatine into something else, yet the Kodak Co. have gone so far towards achieving the impossible that the new paper behaved in the manner of a normal P.O.P. when the weather had brought the temperature of our water supply to over 70 deg. Fahr. Under these conditions there was no reason, so far as we could see, for abandoning the sulphocyanide bath, nor none for fearing that the prints would suffer from their sojourn in the tepid solutions. The new paper is supplied in glossy and matte, the former in white and mauve, the latter in mauve only, and it is also obtainable in glossy and matte postcards.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
15.....	Manchester Amat. Photo. Soc.	Outing to Liverpool.
15.....	Hull Photographic Society .....	Outing to Wansford.
15.....	Blackburn Camera Club .....	Outing to Osbaldeston Woods.
17.....	Bowes Pk. and Dis. Ph. Soc. ....	"After Treatment of the Negative," E. W. Taylor.
17.....	Bradford Photo. Society .....	"Time Development." J. F. Seaman.
17.....	South London Photo. Society....	"Inford Lantern Plates." A. Brooker.
17.....	Luton Camera Club .....	"Exposure and Development." Demonstrated.
18.....	Manchester Amat. Photo. Soc.	Discussion on "One Man Show."
18.....	Hackney Photographic Society	Excursion Prints Judged and Criticised.
19.....	Worthing Camera Club.....	Exhibition of Pictures by G. H. Capper.
19.....	North Middlesex Photo. Soc. ....	Outing to Coombes, Botoilphs, and Bramber.
19.....	Hove Camera Club .....	"Enlarged Negatives." Mr. Chas. Beadle.
19.....		Outing to Chichester.

EDMONTON AND DISTRICT PHOTOGRAPHIC SOCIETY.—On August 29 Mr. William Quin gave a lecture on "Photography as a Hobby and as an Educational Factor." The lecturer said that of all hobbies photography was one of the most intellectual, and as an art-science it had stood for years. He took it for granted that all present that evening had taken up photography as a favourite pursuit, for on that rested a great deal as to what their hobby was to each one of them individually. It was no uncommon thing to hear of persons taking it up with enthusiasm; but, directly that was exhausted, all their love for their hobby was gone! Then there were those who could not make any headway with it. And why? Simply because they were half-hearted. They did not possess the heart, nor the strength of will to take it up seriously and see what they could make of it. Photography, said the lecturer, is not only interesting but also instructive, inasmuch as it reveals to the eye all that is beautiful in nature. Viewed only as a hobby, it is certainly one which fascinates and gives pleasure, not only to its votaries but to others as well. Speaking upon the subject in its relations to education, the lecturer said that of such importance had photography become that it had been assigned a place in more than one higher grade school, and doubtless the time was not far off when it would be a subject in the syllabus of every public school. Certainly some of our best institutions had included it in their course of instruction. It might be truly said that for years past photography had increased so much in importance that it had now become a great factor in all educational studies. A writer, speaking of photography as an aid to study, said:—"The future of photography was absolutely boundless. Already it was spreading with marvellous rapidity into every part of the habitable globe. It was the handmaid of science, and a useful adjunct in many departments of industry. To the traveller and explorer it was indispensable, recording, as it did, truthfully the scenery which, perhaps, never before had man gazed upon. In the lecture room, laboratory, etc., it was fulfilling a useful mission. It had even penetrated the sanctuary and temple, and by means of the optical lantern, had been made the means of useful teaching to thousands."

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The annual conversazione in connection with this flourishing society was held last week at

Collyer Hall, High Street, Peckham. The large company of members and their friends was presided over by Mr. C. H. Oakden, F.R.P.S. He explained that by an unwritten law the winter session was always opened by such a function, the society ever endeavouring to cultivate social intercourse. To many of their excursions and so on, he explained, ladies could be invited, the day winding up with "high tea" and a concert. Songs were rendered by Messrs. Laurence Harewood, Mark A. Kinghorne, and Harry Gale, solos on violin and mandoline respectively were given by Messrs. H. Wicks and Albert Stoneham, Messrs. Kinghorne and J. M. Snellgrove recited, Mr. Henry d'Albert exhibited his powers as conjurer and ventriloquist, and Mr. Charles F. Dickinson gave an interesting and amusing lantern lecture on "Some Excursion Reminiscences"—one picture showed the secretary of the society, in the conscientious discharge of his duties, carrying a lady across a shallow brook. The syllabus indicates a very attractive programme, those lecturing, etc., including Messrs. H. Snowden Ward, F.R.P.S., C. Marshall, A.R.I.B.A., H. W. Bennett, F.R.P.S., etc. A number of interesting excursions have been arranged.

## Commercial & Legal Intelligence.

"For cheap photographs go to Blases."—Such were the words, printed in large type, posted on the windows of one of the principal shops in Heywood Market-place, some months back. For a time the shop seemed to do a roaring business in miniature photography, but there was a falling off in the volume of trade, and the proprietor left. The Heywood Corporation, however, found him, and last week, at the local court, Thomas Blases was summoned for owing £1 17s. 4d. for district rate, £1 1s. 8d. for electricity, and £1 3s. 10d. for gas. The defaulter, it was explained, had gone to the Isle of Man, and the summonses had been served by the Manx police. During the conversation which ensued between the magistrates and the Corporation collector, it was explained that a letter had been received from a solicitor at Douglas, stating that Blases was going into bankruptcy. As a matter of fact application was made at the Vacation Court, Douglas, last week, for Blases to be adjudged bankrupt, and it was stated that he had been in business at Douglas for fifteen seasons. His liabilities amounted to £300. As there were no assets his Honour adjourned the application. The Heywood magistrates have also adjourned the summonses against Blases for twelve weeks to see what comes out of the bankruptcy proceedings. Councillor Coupe, one of the justices, remarked that it was no wonder people got cheap photographs.

**RETOUCHING PHOTOGRAPHS.**—In the City of London Court, on Thursday in last week, before Mr. Tattershall, Mr. T. B. Brown, photographic artist, 163, Queen Victoria Street, sued William Bartlett and Son, chair makers, High Wycombe, for the sum of £1 5s. for work done in connection with certain photographing of Chippendale furniture which had been sent them by the defendants. The plaintiff's case was that the photographs in question were sent them and they were given carte blanche to do what they could in bringing out the details. This they did by making enlargements which were touched up by them. The defendants could then, had they chosen, have had the photographs reduced to what size they liked. It was understood that the defendants required the photographs for a high class catalogue. The work had been done and the defendants had sent them 10s. which they had credited. The proper charge for the work done was £1 5s., and after giving credit for the sum paid there was 15s. still due. The defendants' representative said that the photographs as sent by the plaintiffs were absolutely useless for their purpose, they having been enlarged. The chief charge made by the plaintiffs was for retouching photographs, but the plaintiffs had not retouched the photographs which the defendants had sent them, but had retouched the enlarged photographs. They had since sent two similar photographs to Messrs. Spottiswoode with an identical letter of instructions, and they had the work required to the photographs, charging only a sum of 5s., and they had been given the order. The plaintiff's representative said that the only way to bring out the details in the photographs sent them by the defendant's was by enlarging. Mr. Bonn, called for the plaintiff, said that the defendants by their letter gave them carte

blanche to work the best possible result from the photographs they sent them. The size of the photographs were three inches. As the plaintiffs wished to get the very best result, the only way for them to do was enlarge them double the size to see that the tails were properly retouched after enlargement. There was no need to prevent the defendants reducing the size of the enlargements and the photographs resulting from the enlargements would be the details much better. The artist who had done the work for the plaintiff, called as a witness, said he thought the original photographs sent them by the defendant had been taken by an amateur with a kodak camera. The photographs were small and indefinite detail. For the defence, it was said that the instructions given to the plaintiff was to retouch certain photographs which were enlarged with a letter. Before doing the work which the plaintiff wanted, they should, the defendants contended, have written asking for instructions. The defendants admitted that they told the plaintiff to do the best possible work to the photographs enclosed. The Assistant Registrar said that the defendants in their letter of instructions began by saying that the photographs wanted for high-class catalogue work and they were also asked that the work should not be stinted. The plaintiff and his witnesses told it was necessary to enlarge the photographs and reduce them to the original size. He thought the defendants' instructions were somewhat vague and he thought the plaintiff was justified in doing the best he could with the photographs. Judgment was entered for the plaintiff for the amount claimed, and an allowance was made of 10s. for the witnesses.

**A POTTERIES BANKRUPTCY.**—The affairs of Mr. S. J. H. Ellis of 48, Morland Road, Burslem, now 12, Bleak Street, Stoke, came before the Registrar at the Hanley Bankruptcy Court last week. The statement filed by the debtor disclosed gross liabilities amounting to £144 3s., all of which is expected to rank for dividend, assets estimated to produce £38 3s. 5d., leaving a deficiency of £105 19s. 7d. The alleged cause of failure were "illness of my father and insufficient business to meet my expenses, also competition of a local photographer." Debtor said he commenced business as a photographer, at 48, Morland Road, about June, 1902, prior to which time he had been employed by his father, Mr. S. Ellis, photographer of Hanley, for seventeen or eighteen years. He had a small capital and purchased a few effects from the previous occupier of the premises for about £15. The business was chiefly credit, being for manufacturers than portraiture. He carried on business until April 26, when he made a deed of assignment to Mr. Albert B. accountant, of Tunstall. He estimated that the illness of his wife had entailed an expenditure of over £50. The fact that another photographer of the same surname as himself had set up business in the town had materially affected his business. A statement in a letter to an Ealing creditor that he had that day sent out accounts for £96, and that he had got plenty of orders to go on with was untrue. The Registrar said that debtor ought to be ashamed of himself for writing such a letter. It was nothing but an abominable fraud. The examination was closed.

**MR. GUY RAWLINGS,** a photographer, of Chichester House, Chancery Lane, has had fame thrust upon him through a theft committed in his studio last week. Mr. Guy Rawlings was seated in his studio when he heard a curious sound behind a background. Immediately afterwards there was a noise on the stairs, and he saw the prisoner going down, carrying in his hands a bag and umbrella he had stolen from the studio. Mr. Rawlings followed and gave the prisoner into custody. The prisoner said that he would plead guilty, but would not say how he was tempted to commit the theft. "On July 18 I was liberated from Pentonville Prison after doing twelve months for stealing an overcoat. When I was liberated I had ten shillings in my pocket, and went to stay at a London County Council lodging house in Parker Street. After my money was gone two men who sell papers in the neighbourhood of Chancery Lane gave me papers to sell for them. About a fortnight ago Mr. John Burns—the Cabinet Minister—drove up to the Parker Street lodging house in a cab. I think he stayed in the lodging house for about a quarter of an hour. When he came out and got into the cab that had been waiting for him, one of the lodgers said to Mr. Burns, 'What do you want here?' Mr. John Burns said to the man, 'If I get out of this cab I'll put my fist on your nose.' On hearing this I

said nothing, and Mr. Burns drove away. About ten minutes after this I went up to the man and said to him, in a straightforward way, 'You had no right to speak to Mr. John Burns like that.' The next day I went for my papers as usual, but both the men who had been employing me told me I had better go to Mr. John Burns for a talk. I only tell you this to show how I lost my employment, and was tempted to steal." Sir Albert de Rutzen: You are committed for life.

#### NEW COMPANIES.

**H. B. DAWSON, LTD.**—Capital £2,100, in £1 shares. Objects: To acquire the business carried on at 85, Fore Street, E.C., as J. H. B. Dawson, and to carry on the business of drapers, mercers, hosiers, hatters, photographers, haberdashers, dealers in leather goods, cutlery, stationery, jewellery, instruments of utility or amusement, &c. No initial public issue. Registered office, 85, Fore Street, E.C.  
**ROBERT H. EDGAR, LTD.**—Registered August 30. Capital £5,000, in £1 shares. Objects: To acquire the business carried on at 128, George Street, Croydon, by R. H. Edgar and H. Roberts, to adopt an agreement with the said vendors, and to carry on the business of electrical and mechanical engineers, manufacturers of and dealers in electric, photographic, and other appliances and apparatus, etc. Initial public issue. Registered office, Stanley House, Eldon Park, Croydon, Surrey.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### MR. INSTON'S PHOTOGRAPHS.

To the Editors.

Gentlemen,—I was pleased to see from the JOURNAL last week that Mr. Inston is showing his photographs at Liverpool, and I hope that photographers in the North will not feel that the two London exhibitions so overshadow any provincial show as to neglect the opportunity of seeing the work of the secretary of the Liverpool Amateur Photographic Association. Though I am not a member of that society, and have had the opportunity of knowing Mr. Inston's work only as I have seen it at exhibitions in different parts of the country, yet I would like to say that the younger men who are cultivating pictorial photography should not omit to appreciate Mr. Inston's attitude towards the gospel of dodge and "fake," of which I continue to hear much. If I may quote a remark once made by my hearing by Mr. Inston it will show the method pursued by our Liverpool friend—and it is one in which I am in most complete sympathy. It was: "I would rather kick my heels on a quay for an hour waiting for the right combination of sky, light, and so forth, than get all these separately and laboriously combine them into a single print." Perhaps I may be old-fashioned, but I am of the opinion that in this way the photographs which are to be reckoned as triumphs of our art in the future are being made.—I enclose my card, and remain, Gentlemen,  
 NORTHUMBRIAN.

September 10, 1906.

**ROTARY Photographic Social Club.**—The first sports meeting held under the auspices of the Rotary Photographic Social Club, in conjunction with the works at West Drayton of the Rotary Photographic Club, Ltd., was held on September 1. A large number of swimming races, and other contests took place, and the grounds of the club by the river at Yiewsley were given over to a succession of entertainments which did not conclude until late in the evening. The prizes were distributed by Mrs. E. Haelen; and Mr. Haelen, in acknowledging a vote of thanks to his wife, expressed the pleasure which it gave both of them to be among their staff.

**MR. H. G. LEVINGS**, secretary of the Gravesend Photographic Society, advises us of his change of address to 27, Perry Street, Gravesend.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- F. FOOT, 6, Pitt Street, Jersey. Photograph of the Arrival in Jersey of the 47th Line Regiment of France.
- S. W. B. JACK, 32B, Lowther Street, Carlisle. Photograph of the Insignia of the Corporation of the City of Carlisle.
- F. ROBINSON, Gainsborough House, High Street, Camberley, Surrey. Photograph of the Opening of the Frimley Urban District Council Offices. Photograph of Sir Nathaniel Barnaby, K.C.B.
- E. V. PARKIN, 58, Wilkinson Street, Sheffield. Photograph of the Sheffield United Football Team; Seventeen Players Constituting First Team, with Secretary and Trainer. Photograph of the Sheffield United Football Team. A Group of First Team and Reserves with both Trainers and Secretary.
- T. DOVE, 136, Strand Road, Bootle, Liverpool. Photograph of an Electric Train from Liverpool and Southport.

**TYPES FOR NEGATIVE TITLES.**—I should be pleased if you could inform me where I can procure a book of various styles of printing suitable for titling theatricals' photographs for exhibition purposes.—B. M. W.

You had better apply to John Haddon and Co., Salisbury Square, London, E.C.

**LANTERN SLIDES.**—Having made a holder for lantern slides during binding operations I have been advised to patent same. Will you be kind enough to give me full particulars of patents, and about what it is likely to cost, and oblige?—CONSTANT READER.

If you apply to the Comptroller, Southampton Buildings, London, W.C., he will send you the offered circular of instruction and charges.

**AN OLD OIL PAINTING.**—I herewith enclose you photograph of an oil painting, which I have in my possession. I have had it viewed by several experts, who say it is a very well-painted portrait. (1) Was there an artist of any note about 1759, in the name of Pinsita? (2) What nationality is the name Pinsita? (3) Has there been any pictures sold lately (say these last few years), as I have been informed there has of that name? (4) Could you give me a rough estimate as to its value? Also the best means of disposing of it?—CHAS. MILLS.

You had better write to Mr. Augustin Rischgitz, The Studios, Linden Gardens, Bayswater, London, W., sending the photograph and asking if it is worth while to have the painting valued.

**PATENTS.**—I should esteem it a favour if you would kindly inform me of the most inexpensive way (provided it is safe) of protecting a machine for photographic use, which I wish to offer for sale.—LUCERNAL.

Your best way is to obtain provisional protection at the Patent Office. If you write to the Comptroller, 25, Southampton Buildings, London, E.C., you can obtain a form of instructions and particulars of the cost.

**COPYRIGHT.**—A certain firm have published a picture postcard, showing a young lady and gentleman in a certain pose, with a certain wording on the bottom of the card. Should I be in any way infringing their copyright by taking a lady and gentleman in a similar position—viz., embracing each other and appending the same wording? The latter is of a commonplace order, such as anybody might write on a postcard. (2) Are the works of Francis Ridley Havergal copyright? I have been informed they are not, and can be used by anybody.—H. H.

(1) So far as the photograph is concerned, you are at liberty to take a similar negative from your own models. We could answer you more decisively as to the postcard if you had sent us

the original, which you propose—we cannot say much for your sense of morality—to copy. It is conceivable that the whole card, wording, photograph, and any drawing may be registered as a design, and your production may prove to be an infringement of that. You will have only yourself to blame if you get into trouble. (2) We cannot say.

**STUDIO QUERIES.**—Kindly give me your advice on the following:—

(1) I propose to build a portable studio, like sketch sent, 25ft. long x 11ft. wide, 8ft. 6in. to eaves, 12ft. at highest point, sloping to 11ft.. If built like sketch that would give 10ft. x 8ft. of glass, together with 8ft. x 4ft. of side light, 4ft. 6in. from ground. I am advised to build it like that, as the 1ft. 6in. would give a nice shadow. I should start with glass 3ft. from end, then 8ft. of glass, then fill up the remainder with wood and galvanised iron. Do you think this will do? If not, kindly say how you recommend me to build it and get a good north light. (2) A suitable colour to paint the interior, as I shall matchboard it. (3) I am buying a 12 x 10 camera, which I should want to use indoor or outdoor; chiefly for groups, outdoor. Would a good R.R. lens do for both? Must I have a portrait lens for the studio, or would the portrait lens do for outside work? Any information will greatly oblige.—NEMO.

(1) The 1ft. 6in. at the top of the studio might well be increased to 2ft. 6in. or to 3ft. It would be better to start the glass about 4ft. 6in. from the end, instead of 3ft., as you propose. By having but 8ft. of glass you will be confined to working one end of the studio; hence your light must be from one side only. (2) French grey will be a good colour. (3) A portrait lens is not a suitable one for outdoor work, and a R.R. is a slow one for studio purposes, though it is sometimes used. We should recommend you to have a portrait lens of 11in. or 12in. focus for the studio, and a R.R. or one of the anastigmat type, of about 16in. focus, for outdoor work. With the former you will be able to take full-length cabinets, and, stopped down slightly, whole-plate pictures; with the latter 12 x 10 groups.

**COPYRIGHT.**—We should be glad of your opinion as to whether we have a good case for infringement of copyright under the following circumstances:—Some time ago you made the enclosed photograph copyright for us. In the course of business we supplied the view, which we have marked, to a local stationer, with permission for him to use same for postcards. Recently, without our permission, he has handed the block of this view, amongst others, to the “\_\_\_\_\_” for them to illustrate an article on Woking. We are in correspondence with the proprietors of this paper, and in their last letter they say they are writing the stationer, as he gave them permission to use the views.—A. W. AND CO.

It is a clear case of infringement. We should advise you to accept a guinea for the reproduction from the publishers; or, if they refuse to settle promptly on these terms, to make it two guineas. The paper has no case at all.

**PLASTER CASTS.**—Will you please tell me in this week's issue of your paper where I can get the plaster cast as recommended by Duchochois; also the price of same? I only want a head and bust to see the effect of lighting.—G. E. F.

From one of the Italian firms round Hatton Garden, such as G. Baldacci, 31, Hatton Wall, E.C., or D. Landi, 36, Charles Street, Hatton Garden, E.C.

**COLLODION EMULSION.**—Could you, through the columns of your valuable paper, give me a formula for unwashed collodion emulsion that will work as quickly in exposure as the wet process? I have tried several formulæ, but they are too slow.—C. B. CLIFFORD.

We are very doubtful if you will be successful in making an unwashed collodion emulsion that will equal the wet process in sensitiveness. However, the following is a good formula for an unwashed emulsion: Ether, 720, 5 ozs.; alcohol, 820, 3 ozs.; high temperature pyroxylene, 50 grains; bromide of zinc, 76 grains; sensitise by adding 120 grains of nitrate of silver, dissolved in half a drachm of water, and an ounce of boiling alcohol. After the plates have been cooled and washed, immerse them in the following: Tannin, 150 grains; water, 10 ozs.

A. W. ADAMS.—We should certainly advise either of the reflex

instruments, both of which are first class. You should have a larger aperture for the lens,  $f/5$  or  $f/4.5$  is as large as ad and you cannot do better than select a lens, the separate elements of which can be used of this aperture. You are able to select an anastigmat of focal length suitable for camera and of this aperture from the makers' list in the ALMANAC.

**A DEFECTIVE NEGATIVE.**—I intensified a negative, bleaching with potass bichromate, and re-developing with amidol. Unfortunately I omitted to add the soda sulphite to the amidol, staining the negative. I dipped the negative into the hypo, which brought it down very thin. I now require to intensify it again. I am so very thin I am in doubt what method to adopt.—BRAD.

As the negative is a mere ghost, we should recommend you to use the uranium intensifier, as per the formula in the ALMANAC. You had better treat the plate to a weak bath (1 in 50) of acid for ten minutes, and afterwards wash it for half an hour in order to bring into the best condition for intensification.

**DEALER.**—See our advertisement columns, in which you will find announcements of the kind you seek.

**COPYRIGHT.**—Will you kindly inform me, through your valuable journal, whether the following subjects are copyright or are free for publication? “Moses in the Bullrushes,” “The Huguenots,” “The Black Brunswick” (Millais), “Before the Bath,” “After the Bath” (French subjects).—E. R. EDE.

Copyrights in the original paintings have no doubt expired, but we do not imagine that the copyright in copies of the paintings has yet run out.

**PLATINUM RESIDUES.**—Will you kindly inform me, through your journal, the best way to throw down the platinum from an aqua-toning bath?—PLAT.

A solution of ferrous sulphate (green vitriol) is added to the mixture brought to the boil in an enamelled iron saucepan. The platinum is thereby thrown down as a heavy black powder.

**PYRO.**—In our next.

**FLASHLIGHT.**—I have been asked to take a flashlight photograph of a bazaar at night, in a room about 50ft. long and 30ft. wide, and should be glad of your advice. There is a platform at the end of the room, from which I propose to take the photographs. There will be a number of people in the room at the time. What kind of apparatus to use? (2) What kind of powder to use, and the quantity? (3) The best plates to use and the shutter exposure for them? (4) Should I be right in placing the flashlight at the back of the camera and a little to one side? Would the gas have to be lowered?—BAZAAR.

(1) Unless you care to go to the expense of a good lamp, such as the “Weiss” or “Warwick Brooks,” your best plan will be to use a good flash powder, spread in a line in a shallow trough, made from a strip of thin sheet iron. (2) A good brand such as the “Agfa,” “Argentorat,” or “Ideal” (Houghton & Co. Ltd.). About a quarter of an ounce of the powder should be sufficient, with an ultra-rapid plate, and the lens at  $f/11$  or  $f/16$ . (3) Any plate sold by the makers as the most rapid of the brands. (4) Yes, and a good height from the ground, 8ft. to 10ft. if the height of the room will permit. (5) Gaslights in globes may be included in the picture, but we think they detract from the effect of the photograph.

**\*\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The P.P.A. Exhibition at the BRITISH JOURNAL.—The last day for receiving prints is Wednesday next, September 26. Packets should be addressed to 24, Wellington Street, Strand, W.C. Will each member of the P.P.A. make a point to send one print? The exhibition opens October 11.

The Photographic Salon.—The real sensation of the Salon is the marvellous decorative work of F. Benedict Herzog, Nos. 76 and 147. Detailed criticism of the exhibition commences on page 745.

The R.P.S. Exhibition.—The fifty-first exhibition, which opened yesterday, shows a greater variety of good work than has been seen in several years. (P. 741.)

Photographers' Show Cases.—A few prints, arranged to harmonise with the internal coverings, are advocated in an article, which explains how a seaside photographer employed show cases profitably. (P. 743.)

F. Dundas Todd, in an address to an American convention, analyses the costs of production of photographs in a studio, and urges a strict surveillance of the separate departments. (P. 748.)

The claims of photogravure to the serious attention of professional photographers are emphasised in a note on page 743, in which it is suggested that the supply and printing of photogravures might be taken up with profit by a process worker or photographer. (P. 743.)

The coupon fraud has been active in the suburbs of Birmingham. (P. 742.)

Dr. Frederick Graves gives the formula for a concentrated combined bath for the rapid toning of P.O.P. (P. 745.)

An exhaustive work on pigment printing processes, by MM. Demachy and Puyo, has been published. (P. 755.)

Preparations are being made at Hereford for the 1907 meeting of the Photographic Convention. (P. 753.)

A further development of catatype is among the patents of the week. (P. 754.)

## EX CATHEDRA

### The Royal Photographic Society's Exhibition.

A comparison between the pictorial section of this exhibition and the Photographic Salon is not only natural, it is inevitable. The latter society is an avowed rival and, therefore, emulation and competition are rife. Were it not for this rivalry the work in both places might suffer, for it is an undoubted incentive. We believe that the general opinion is that the present show of the R.P.S. reaches the high-water mark of merit in the annals of that society—now pressing towards its second jubilee. The galleries are certainly arranged and decorated with faultless taste. The little columnar arrangements of figured silk tape show what thought has been devoted to artistic points that will escape the crowds who come to see the pictures. There are no sensations at the New Gallery, unless the portraits of Mr. Coburn constitute a mild one. He greets us jauntily—a veritable "Last of the Dandies"—as we enter; and he deplores our departing—on the companion door-jamb—as we leave. Those who have been unlucky enough ever to glance into the distorting mirrors outside some popular eating-houses, will have some idea of the varying expression on Mr. Coburn's respective faces. What makes the strength and attractiveness of this display is very largely the great variety in the classes of work shown; the different points of view from which the exhibitors regard picture-making by photography, and the great influx of newcomers, many of whom are from abroad. The last point is one of supreme gratification, for it shows that our mother society is not a hole-and-corner business; but has the appreciative recognition of the world. Herr Paul Pichler makes a far finer show here than at the Salon, to which he has not been kind. His "San Vigilio," and "Der Waihter," are things so fine as to remind us of the late Boecklin, whose magnificent compositions they greatly resemble. Dr. Ledenig is another foreign factor in the success of the show. For romance and true feeling it takes the first place. Herr Feledi makes a welcome third, and Sig. Ornano a fourth.

\* \* \*

### A Few of the "Plums."

The style of print that used to be known as the "treacle" style, a sticky-looking juicy-brown production, has almost entirely passed away. We remember the time when nearly all the pictures in the "Royal" galleries were of this kind. Greys now hold the field, and white mounts are frequent, whilst the passe-partout method is conquering the heavy old oak mouldings. One or two little silvery prints recall the steel engravings of fifty years or more ago, a proof that we are on the eve of a great Early Victorian revival. "La Forêt Enchantée," by M. A. Gomez, emulates a style

still a little older. With its romantic subject, its white mount, and title adornments (by photography also), it is a very pleasing fancy cleverly carried out. Dr. Evershed's "The Crane," shows how much can be done by judicious selection to make a modern ugliness play a beautiful part in a picture. This ability belongs also to Mr. Batkin, whose omnibuses in "A Rift in the Fog" are things of beauty. Nudes are not numerous here, but the nicest treatment of them is by Miss B. Johnson. She has placed them in a little idyllic landscape, and given them a classic touch by making the chief one play upon the ancient Greek double pipes. Mr. Mummery's landscapes are better than usual, which is saying much, indeed, and those by Mr. Stuart are noteworthy also, especially where he does not allow himself to lose effect, which is, after all, the charm of landscape work and is well looked after this year. The visitor will find that there are not more than half a dozen pictures without some feature warranting their place on the walls, whilst the good things strike him with remarkable frequency.

**Municipal Photographs.** An interesting sequel to the recently advertised offer of the Cardiff Town Council to purchase a set of six specially attractive photographs of the borough for £5 is reported in the current Cardiff papers. Five pounds was the munificent sum which the Council dangled as a bait to the local photographers, and this sum was awarded to one of them. The prints, however, were not considered good enough, and a professional photographer, Mr. W. Jenkins, was asked by a committee to supply a set for £25, the whole Council subsequently deciding that the photographers of the town should be allowed to compete for this sum. The questions now before the astute councillors of Cardiff are: "Who is to pay Mr. Jenkins for the work he has done?" and "Are the local photographers to be allowed to compete for the work, part of which has been done by Mr. Jenkins?" We hope some of our photographic friends will profit by the indiscretions of the Cardiff Council.

#### The Coupon Fraud in Birmingham.

Our article of last week on the frauds recently perpetrated in the eastern London suburbs apparently applies to a man who is working the game near Birmingham. We learn that a man has been canvassing the poorer classes at Aston, getting orders, so he alleged, for a photographer in that suburb. He quoted charges which were one-third those of the photographer—and in

every case managed to collect a deposit of money in some cases no more than sixpence. In some instances people were to visit the studio; in others they were to be called upon, and the result, of course, has been that the self-styled canvasser has decamped with his money. Photographers who may have similar experiences—would seem that this particular man is travelling all over the country—should lose no time in communicating with the police. Unfortunately, by the time the information is received, it is too late to do anything; but it is not unlikely that the fellow imitators may apply to a photographer for the services of a canvasser. Any such application just now may be received with considerable caution.

#### Is There a Remedy for Coupon Frauds?

The years during which the coupon swindlers have flourished unchecked almost discourages any hope that the form of fraud, which is so particularly injurious to photographers, may be stamped out. The trouble, of course, is that the persons who are the victims of the frauds belong to the classes which may be depended upon not to take legal action. It is, as a rule, the servant girls who are the most easily gulled by a plausible tale. The photographer has not sustained any damage, and therefore he cannot take any action, and the victims of the frauds themselves have not the time nor inclination to go to law; they rather put up with the loss of their sixpences and shillings. The question is how is the fraud to be stopped, and the annoyance to photographers to be checked? The only way we can see for photographers in suburban districts to display prominently, in their showcases or shop windows, notices cautioning the public that they do not issue coupons or employ canvassers, and that any persons using their names do so fraudulently. If this were universally done the swindle would soon die out, as there would be no victims to be duped.

#### A Society Fixture.

Secretaries of societies who complain of the difficulty of providing novel fixtures for their members' instruction may be grateful if they suggest how one evening at least may be filled with pleasure to the members. Let the society purchase the new book by MM. Demachy and Puyo, reviewed this week in another column, and frame the supplements in *passé-partout*. Quite an interesting show will be thus provided, to which a local art critic would no doubt come and give his verdict on the reproductions from the non-photographic standpoint.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

The forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, as to be well in advance of the Christmas publishing season, and the co-operation of advertisers to that end will be esteemed by the publishers.

if this cannot be arranged, a member of the society able to read M. Demachy's text could draw up an account of the processes used in obtaining the pictures, and explain the points which they illustrate. The opportunities of comparing the works of leaders in pictorial work with their own confessions of the *modus operandi* occur so seldom, that they should be embraced, and the reproductions in "Les Procédés d'Art en Photographie" are remarkably near in quality to the originals.

**Vandalism by the London County Council.** Comments strong and deep have been made in the daily press during the last week or two on the vandalism to be perpetrated by the L.C.C. in cutting down, lopping, or otherwise disfiguring, the trees on the Victoria Embankment, to make room for their tramway. The L.C.C. seem to give no consideration whatever to the aesthetic, and as they have got their Act of Parliament to run the tramcars along the Embankment, they can do as they like with it. Hence the beauty of London's only real boulevard is to be sacrificed by it. The trees, since they were planted, have grown to goodly proportions, and the embankment has become the happy hunting ground of a large number of London photographers, as well as of photographic visitors to the metropolis. As the cutting down has not yet commenced, and the trees are still in good foliage, those who wish to secure pictures of the Embankment as it at present is should avail themselves of the opportunity while it lasts, which will not be long, as the cars, it is said, will be running by the commencement of next year. It was evidently an oversight, in framing the Act permitting the L.C.C. to run their cars along the Embankment, that a clause was not inserted providing that the trees should not be disturbed in any way.

**Photogravure for Portraiture.** For some time past it has been a matter of surprise to us that high-class portraitists have not, at least to some extent, availed themselves of photogravure for their pictures. This is the more surprising seeing that so much has been published during the past few years on the process, and that it is after all a very easy one to work, while the results obtainable are unapproachable by any other. At the present time, when every effort seems to be directed towards making photographs resemble engravings as closely as possible by printing them on matt papers, mounting them on plate or Japanese papers with India tints, plate marking, etc., there should be a field for true engravings. After a few practical lessons, such as are obtainable at the Regent Street Polytechnic or the Bolt Court School, any intelligent photographer should be able to produce excellent plates of the dimensions required in ordinary portraiture. Briefly, the process is this: From the ordinary negative a transparency is made, preferably by the carbon process; this can be retouched to any extent in the usual way with the pencil, and the shadows strengthened should they require it to increase the vigour of the picture. A copper plate, such as used by engravers, is then grained in the dusting box with powdered bitumen and then heated to fix the grain on the metal. On the grained plate a carbon print from the transparency is developed in the ordinary way—a special tissue for the purpose being now supplied by all the makers of carbon tissues. The print on the metal being obtained it only remains to etch in the image with solutions of perchloride of iron, when it is ready for printing from after the manner of copper-plate printing; and, of course, any coloured ink can be used for the purpose. Should any retouching on the plate be found necessary the lights may be increased by the burnisher, or scraper, and the shadows strengthened

by the roulette, and no great amount of skill is required to do the work. When once the plate is obtained and has been faced any number of prints up to thousands can be made from it, at any time, at quite a nominal cost. They require no mounting. They can be printed direct on plate paper, or on India tint, or on Japanese paper. In appearance they will be quite different from ordinary photographs made to imitate engravings—they will more resemble good old mezzotint prints, which have recently been realising such fabulous prices at picture sales. It goes without saying that our suggestion will only appeal to the higher class photographers who can command fair prices for their productions, though, after the plate has been obtained, prints from it can be produced at the same cost—or less—than by ordinary photographic method, by any copper-plate printer if the photographer does not care to do the printing himself. There should be, we think, a considerable business to be done by any firm who care to make a special bid for the custom of photographers in the way of preparing photogravure plates and taking off the impressions.

#### The Picture Postcard in France.

We shall expect to learn, when the next annual report of the Postmaster-General is issued, that the present is a record year for the number of picture postcards that has passed through the English office. The craze for picture cards seems to be even still greater in France than it is in this country, if we may accept the statement of the "Standard's" Paris correspondent, who, writing one day last week, says that in Paris alone 1,500,000 picture postcards were delivered daily during the months of July and August. This, he adds, is equal to an average of more than one card for each adult inhabitant. It is also mentioned that the increase on the daily average between April and July was 500,000. Whether these figures are equalled in London may be open to question, but there seems no evidence of the popularity of the picture postcard waning in England at present.

#### THE PHOTOGRAPHERS' SHOW CASE.

In two previous articles, which appeared in the "Journal" for August 10 and 31, we spoke of the considerations which should govern the photographer in selecting and arranging the display of his works in his window. Many of the opinions there expressed apply also to the show case, but some further notes on this adjunct to a studio seem to be called for, since there are many photographers who, through local circumstances, are forced to use a show case in place of a window for displaying their works, and others who, though possessing a window, have show cases in various parts of their town quite apart from their place of business. It is to these latter that the following is mostly directed, the former having usually elaborate cases which are almost amenable to the same treatment as a window. These will, perhaps, find our former papers of some use.

When there is no window attached to a gallery it is usual to have the cases at the doorway and in the porch, the situation making it necessary to have two or more separate and distinct cases, which is a decided advantage. Each case effectively separates its contents from the others, and it is thus possible to make a widely different and yet harmonious exhibition. Each case, however, must be treated by itself and the contents receive careful thought when the choice of specimens is made.

The show cases themselves do not require much discussion, since local conditions usually govern the choice of size and shape. It is preferable, however, when the

case is to be hung on to a wall, that the glass be hinged to the frame so as to open without removing the whole. When heavy fronts are in use the hinges should be of the best pattern, and a small strut be fixed on to the lock end of the door so that when the door is opened this strut will pull down and support the weight of the glass rather than put all the strain on the hinges. When the case is supported on pillars or posts, so that the back is easily accessible, it is better to have the glass firmly fixed and the back made to open, there being less weight and less chance of the glass breaking. In both of the above cases the show board upon which the pictures are fixed (we are not here discussing deep cases to take enlargements and small pictures on shelves) is loose and movable. There is another type of show case which is made to hang on a railing, the show board itself being made to serve as the back; being, in fact, similar to a very large picture frame. These are not recommended, as they are awkward to change and are liable to admit wet.

The inside of the case or the covering of the show board is usually of some textile material. The old-fashioned red plush is luckily not now much used. Nothing could be worse for the purpose, and the use of it is a sign of most lamentable taste. Red is the colour above all that will clash and kill almost every style of monochrome and all coloured work, except perhaps the strongest oils, and as we all know, red plush is the most vivid and shrieking of any type of red material. What is wanted is some quiet smooth-surfaced material that will serve its purpose for covering up the rough board and isolating the pictures upon it, while it is itself inconspicuous. Any of the art serges are cheap, and keep their colour fairly well. Art canvas in certain shades is extremely good, whilst common holland can be used with a very few colours of mount and print. The colour to be chosen depends entirely upon the colour of the mount and print to be placed upon it, and is determined upon the same principle as the selection of a mount dealt with by a writer in the "Journal" for 1905. The colour may either harmonise or slightly contrast, according to taste. For brown prints upon brown mounts dark green is a good colour, or old gold, but do not get a brown too near the shade of the mount or the object is defeated and the repetition of colour irritates, and moreover the print will tend to sink into the ground. With a contrasting print on a brown mount the cloth may well be brown; this gives the effect of a larger mount; or the cloth may be of the same tone as the contrasting prints; this gives the effect of a board round the print effectually isolating it from its neighbour. With a brown print on green mounts either a brown or green cloth is indicated. With brown prints on cream or other light mounts brown cloth gives the best effect. If green were used, practically three colours would be introduced, and the less colours one has the easier it is to make a tasteful and harmonious show.

It will be noticed above that we have only mentioned one colour of print on a certain cloth, and then the reader thinks, "Yes, but I want several coloured prints and mounts in one case, what then am I to do?" The answer is, don't do it. This throwing in of different tones of prints and mounts into one small case where the case itself is considered as a whole before the contents are noted is the great cause of unsatisfactory and inartistic displays. The result is almost sure to be clashing discord, and when viewed from a short distance the effect will be spotty and distracting rather than giving the effect of one harmonious whole. If the reader will examine those show cases that appear to him to look the smartest and best, we are sure that he will find that the contents are almost invariably on one tone of paper, and on mounts exactly

similar in tone and texture, though, of course, differing in size, shape, and style of trimming. A few selections of varying colours can be placed in a case so that the result is pleasing, but to the majority of photographers we say, "Don't." One gets repetition in way, and if every print were exactly similar in style, subject, and subject, the result would merely be monotony. One gets repetition with variety by having (as of course one must) each portrait of a different sitter, and 'rimming' prints in different shapes, as well as by including cartes, cabinets, 1/1 plates, and panels in the case.

Another cause of unsuccessful displays is the overcrowding of specimens so that none have a fair chance. This overcrowding is very prevalent and quite unnecessary. A small number of prints with space between them is much more pleasing than if each mount be placed quite close to its neighbour. When setting out the boards cabinets will probably be the backbone. See that they include a variety of shapes—cabinet, panel, circle, etc., and also use some 1-1 plates or panels to break up the spaces. It is very usual when preparing to fix the photographs to work from the middle, having exactly the same sizes and shapes in each quarter of the board. This is bad and should be avoided. The result is stiff and lacking variety. Avoid all appearance of geometrical patterns; it is far better to insert photographs with a studied carelessness. Of course, the horizontal and perpendicular lines must be correct, or the effect is slovenly, and this is not the idea we wish to convey. The spaces between the mounts should not be all equal but well varied, neither should the side or the top and bottom of a mount be in an exact line with the sides or top and bottom of the mount adjoining it. Take care, however, that the difference is so marked as to seem intentional and not appear to be due to carelessness.

The above remarks may be applied equally to boards of paper mounts, but prints mounted on paper require even more room than the ordinary mount to show to the best advantage. If about a dozen cabinets are placed in a case 6ft. by 4ft., well separated and not symmetrically placed, the effect is very good. These mounts should be fixed with drawing pins to obtain the full delicacy of effect. Gimp tacks, either brass or black, are suitable for the boards.

Show cases are particularly suitable for rapid change advocated in our last. One photographer at a pleasure resort where the population is always changing has eight or more boards to fit one of his principal cases. Each board is fitted with different specimens:—Sepia carbon on (1) cream, (2) brown, (3) paper vellum mounts, (4) sepia carbons with Cosway border, (5) black platinotype or carbon on rough white paper mounts, (6) black print on grey mounts, (7) red carbons on paper vellums, and so on and so on. With green carbons, collodion and silver prints, rough brown and green deckled edge mounts, also two or three board mounts and specialities of his own there is no end to the changes that can be made. And all this costs him no more than the usual six or seven changes given to a case in a year, for each board goes into the case for a day only in turn until it comes round to the first board again, when each is passed through. In this way he has a complete change every day for eight or nine days, and the sequence is arranged so that the board placed in the case on one day is as different as possible from the photographs shown on the preceding day. In this way visitors will see a different show perhaps every day of their stay, and not knowing the secret, are bound to put the exhibitor down as a pushing man. This method of having several boards for one case can also be used for specialisation, as suggested in the note on shop windows.

## CONCENTRATED TONING.

Every photographer, amateur or professional, at some time or other is beset by the worries and difficulties of that simple business, the toning of P.O.P. And often it happens that he has a batch of prints that must be finished quickly.

Though much has been urged against the combined toning and fixing baths, they have one great advantage, and that is that, with very little labour, they will quickly tone and fix, with little washing, when time is precious; and for this purpose it is necessary to employ a concentrated bath.

And in accordance with the amount of concentration, so is the time reduced; indeed, by using a very strong bath the process may be practically instantaneous.

No preliminary washing, at least with most brands of paper, is required, and only a thorough final washing.

But the immersion of the prints must be as quick and even as possible, and though there is not the danger of marking as in separate toning baths, it is advisable to thoroughly and carefully immerse each print at once.

Of course we may use concentrated simple toning baths if we wish, but there is no great saving of time as in the case of combined baths. Supposing we take such a bath as the follow-

ing:—In about 3 oz. of tepid water dissolve 40 grs. soda tungstate and 60 grs. ammonium sulphocyanide, then 6 to 8 drams of hypo; then add one to two grains of gold dissolved in a little water. The amount of gold will vary with requirements as to depth of tone, etc.

The prints should be rather over-printed, as they will sometimes lose a good deal of depth in this bath.

But if properly carried out a bath of this kind at normal temperatures will tone and fix with considerable rapidity, and the range of colours obtained will vary upon the amount of concentration; if we reduce the water the speed will naturally be increased.

But a rapid toning and fixing that will often serve for rough and test work and for proofs will be accomplished in a few seconds. When one comes to study the question of permanency one must admit that there are doubts, but with thorough washing after the operation there is little to fear.

Some very rich brown and black tones may be got in a bath such as above; the blacks, however, require time, and it is rather for quick work without special regard for tone that such a bath is to be recommended.

FREDERICK GRAVES.

## THE PHOTOGRAPHIC SALON.

FOLLOWING up our impressions given in last week's issue, we may confirm our ideas of the chilly sobriety of this usually exciting show. The present lack of sparkle may be due in a measure to the more spacious hanging of the prints and the consequent thinned-out appearance; though that in itself can hardly be deemed a disadvantage. It may be because the decorations are this year of a low-toned brown paper, panelled off by strips of veneered mounting-board; though here again we cannot but admit that in itself this scheme of decoration is very suitable and in very good taste. Indeed, we are disposed to pay a special tribute of praise to Mr. Coburn, who, we understand, has taken upon himself the whole artistic responsibility of the hanging and decoration this year, and the lion's share of the labour too. The fact remains, however, that a visitor, upon entering the gallery, is more than ever struck with the monotony of sober tint that seems always and unavoidably to belong to a show of photographs. He sees so much of this estimable brown paper showing amongst the pictures. He misses those touches of red, green, blue, and yellow which in former years have enlivened the proceedings, however intolerable they may have been at close quarters. There are certainly two attempts at colour by M. Puyo that surprise us as coming from a man of such taste, and one also by Mrs. Käsebier; but these do not count as decorations.

### What is a Sketch?

According to an unwritten law of the Salon, Mr. Will Cadby leads off. His pallid trifles are usually offered first, either as hors d'œuvre to whet the appetite, or else upon that other feasting principle of saving the best until last. Considering the severe selection that must be necessary where so little room is available, we do not feel that much sense of proportion is evident in the hanging of five child studies all so similar in aim and treatment that one alone would very well have been representative of Mr. Cadby's style. His sixth work, a so-called sketch, is to our minds likewise usurping the space of some more single-minded and genuine effort. A sketch, in photography, is just about as absurd and impossible as a flash of lightning on probation in the heavens. A sketch is a preliminary stage in a long process; this "Snow Sketch" is *per contra* the laboured result of elimination. Artistically considered it is a sheer blank; photographically it is a blank soiled with the dregs of photography. By its author it is thought to be worth one guinea. In Mrs. Cadby's work there is more respect for the proprieties. One of her plant studies shows honesty, both as its subject and in its

motive; but it cannot be said that she has secured exactly the characteristic charm of the silky and opalescent seed pods of *Lunaria biennis*. So with the "Shepherd's Clocks," which appear to be spiky rather than fluffy.

Mrs. Fannie E. Coburn has a good sense of style in landscape, but not sufficient susceptibility to the differences of tone values. In her "Eastbourne" the shore has come much too dark we should say, and in "Reflections" the water should not be of the same tone as the sky, to mention only one point. Two very lively and pleasing heads come from Mrs. Jeanne E. Bennett. They are called "Mirth" and "Toby." Her "Soap Bubbles," a little girl seriously occupied with tobacco pipe and suds, is a pretty thing, and a clever piece of work.

### Tomfoolery.

A child, and the lower half of its nurse, is sent by A. S. Goss—from Canada, and therefore the circumstance does not surprise us. But the fact that it should have been honoured with wall space here does surprise us. The most remarkable qualities, had it possessed them, should have damned inevitably such tomfoolery as this, and it probably would have done so were it not that anything in the shape of an American photograph seems so to fascinate the "Links" as to paralyze altogether their critical faculty.

### MM. Puyo and Demachy Experiment.

We are afraid that those staunch supporters of this annual exhibition, Messrs. Puyo and Demachy, have not sent their choicest, this year, or it may be that their choicest have been rejected. At any rate, we would very gladly surrender M. Demachy's experiments in ootype and "oils" in favour of three or four of those charming studies of his in materials of which he is a past master. The very palpable erasures of pigment which do duty for high lights in his present works, and the absence of certain inimitable qualities which are the birthright of photography, leave us a trifle disappointed. Similarly, we take but little pleasure in M. Puyo's "Tête," and the "Portrait," both "en 4 couleurs." The first, as we pointed out last week, is ghastly; the other is tinted without reference to natural truth, and without respect to decorative charm. M. Puyo, however, solaces us in his two other works, "Après Vêpres" and "L'Étang." The latter is a particularly soft and silvery study of willows, having the light and touchy qualities of a sketch in water-colour, but being free from any obvious imitation of a work in that medium. Peasant women squatting at the foot of a market cross or some such

structure is the subject of his remaining contribution. Its only fault in our eyes is a little hardness of line about the heads of the figures.

### One for Detail.

Mr. J. Craig Annan has two landscapes and four portraits. On the whole we prefer the landscapes. "Stirling Castle" is without doubt one of the best in the show. It has all the richness, all the strength, and all the breadth that is sought for to-day by this or that new method of printing; but it has, in addition, the pleasing characteristics of legitimate photographic processes which are nowadays too often allowed to go by the board. Detail, for instance, is one of its chief attractions, not only for its own sake, but for the exquisite rendering of textures which detail only can secure. The little horse, less than an inch long, is sleek of coat and clean of limb. Compared with the wall behind him he furnishes an excellent object lesson in the proper use of detail as an exponent of pictorial facts. "Stirling Castle," in the dignity of its style and the absorbing interest of its minutiae, resembles a copper engraving of the French School in the eighteenth century. "The Thames at Hampton," by the same worker, is good also; but it portrays one of those Martinesque effects that we have now grown callous about in photographic pictures, yet which would set us all aquake with fear if we saw it actually in nature. Of Mr. Annan's portraits we like "The Lady in a Silk Gown" best, though we submit that this might have been finer than it is, had not the lighting been uniform and monotonous.

The landscapes of Mr. Malcolm Arbuthnot lack the saving touch of nature. His near hills and distant hills are positively identical in tone and texture. They therefore violate one of the first principles of landscape art. Moreover, this violation is due entirely to tampering and manipulation—liberties that we hold should only be taken with photographic views by those whose observation and experience save them from pitfalls and solecisms. The best of Mr. Arbuthnot's works is perhaps "Launching the Boat," which has a capital subject; but even here the sky, the shore, and parts of the boat are all of the same tone and texture.

### Poetical Effects.

We frankly admit that Mr. George Davison's "Across the Sand Hills, Harlech," is beyond us. We bow and pass on to "The Mitre, Hampton Court," wherein we acknowledge a poetical effect—something of a "mood," which informs the rainy (?) scene and stirs up memories. There is positively nothing of this in the "bald and unconvincing narrative" of Mr. Pratt's "Pine Branch." Why so empty a thing was framed, and why hung here, we are at a loss to conjecture. Something a little more sustaining is discovered in Mr. W. Bennington's "Evening Mists, Coombe Bottom." Yet in this we find a falling away from the high standard which this clever worker has already established. We do not think the subject of a tangle of telegraph wires worth a picture, however well done, and therefore come with relief to his "Pines," which has in it the true witchery and eloquence of landscape. Upon this work we heartily congratulate Mr. Bennington, for it is at once ambitious and successful. We have marked it as one of the beautiful things of the Salon exhibition. His "Portrait" is also very pleasing.

In "Maltings on the Lea," Mr. John Anderson (now a "Link") has availed himself of exceptionally fine subject matter; but we scarcely think he has made the best of it. He has shown rather too much in his view. We remember a small version of this subject, exhibited by Mr. Mummery a few years back, in the Dudley Gallery. Tiny as that picture was, it had a more dignified selection and treatment than the one now before us. All Mr. Anderson's pictures here suffer from a murky stodginess. On the other hand, Mr. W. B. Post has chosen the better part in "going for" real happy refreshing daylight in his pretty piece, "The Beaver Dam," the best of his three contributions. We are always pleased to see Mr. Chas. Emanuel's bright, clean little views, of which two are here entitled respectively "A Dorsetshire View" and "Corfe Castle."

Miss G. Aitchison's single contribution is so good that we truly wish there were many more of them. Her "Steep Street" is an excellent little picture of an old house with a wealth of paved roadway before it, patched with sun and shade. All its parts are in keeping. Breadth holds the interest of detail within itself, and truth of effect is simply and unaffectedly given.

### From Italy and Germany.

The characteristics of two prints exhibited by Sig. Edoardo Rone, a new name in these galleries, are clean tones, rich and varied, and contrasted with an accent of high light. The first, "Dolore," represents a peasant woman who has thrown herself by a bedside in an attitude of despair. Above her, through a narrow window shaft of sunlight enters striking the adjacent wall. The work has a great feeling. "Bobo de Bèbe" represents, perhaps, the same model who now plays with a child upon her knee. The livelier subject has a livelier display of tones. Both prints are also excellent, considered photographically. Two other works, from Dresden, are strong and different way. They are by Herr Ernst Müller, and one is a remarkable portrait of "Kunstmalers Georg Müller-Breslau." It appears to have been inspired by the intensely vigorous and realistic portraits of certain old German masters, if not by those one or two moderns who affect the old style. No one could deny the virility of this portrait or its intense interest as a human document. It is something quite new in photographic portraiture, and likely, we think, to exert a good influence upon the work of this country which is prone to run after transatlantic vagaries. "Dame am Fenster" is not so extraordinary to British eyes.

### Decorative and Natural Effects.

Mr. Mummery's "Broxbourne" is a composition selected with a cute eye to decorative effect. It comes very happily. There is an unaccountable loss of strength under the right-hand bank that does not seem to be due to any possible play of light at that point, and a little mystifying. A decorative idea exists also in Mr. Brogden's "Railway Station," where the structural ironwork of the station has been turned to happy account in a bright and interesting little picture of railway land. Two seascapes by Mr. F. J. Mortimer are admirable studies, full of light and movement. "Racing Home" is very lively and exhilarating; whilst "Dirty Weather in the Channel" gives very unmistakably the sensations of chill and bluster as spray felt under such conditions on shipboard.

Mr. A. Horsley Hinton is represented by two studies of what may be heath fires in the one case; but is river mists in the other. We derive much pleasure from this departure in subject, though we are not quite sure that the effect is not a little overdone in both "On the Moors" and "Early Morning—Windsor." "A Silent Day," by Mr. David Blount, is light, airy, and otherwise satisfactory; but his "Study of Trees" suffers from Want of any suggestion of distance.

The best of the three works sent by Herr Rudolph Dührkoop is the magnificent "Twilight" that was recently in our own exhibition. Mrs. Susy Mahony sends a delightful view of the Customs House, Dublin, under the title of "A City Highway." It has light, but its somewhat divided composition mars it. Sunlight and shadow are prettily given in the print of a tree-shaded cottage which Mr. C. D. Kay calls "Sunlight," and another cottage subject, called "Autumn," is likewise notable for its light and air. This is by A. H. Blake, M.A. Of his riverside scenes we prefer "The Wharf."

### Living Pictures and the "Altogether."

Having worked through her line of Madonnas, Mrs. Barton has now come to the level of the saints, presumably. We confess to a slight feeling of relief. Specialisation is all very well, but it palls upon the critic. In "St. Catherine" she gives us a figure of a maiden, whose pose, costume, and air is very cleverly reminiscent of early Italian painting. In fact, the deep even tones of the draperies, the hard and edgy treatment of the crinkly veil, the exact adjustment of the model's hand, argues a deal of commendable patience in the setting up of this *tableau vivant*. The result is pleasing in spite of the obvious "get-up," and this says much for Mrs. Barton's artistic sure-footedness in a difficult path. And whilst on the subject of *tableaux vivants*, we may revert again to that other piece of *pose plastique*, namely "Le Penseur." It is an astounding piece of dare-devilry on the part of all concerned. There appears to have been no anxiety, on the part of either sitter or operator, that the well-known features of a much-discussed playwright, novelist, Socialist, journalist, musical critic, photographer's model, etc., should not be recognised. The conclusion is, therefore, that whatever sensation must follow this epoch-making disregard of the proprieties on the part of a public man, must be welcome

to the advertising triumvirate, which includes Rodin, the French sculptor. Truly, they have their reward! The original "Penseur" was an extravagantly conceived piece of staginess, since the thinker ever fisted his forehead in the brutal style of this thinking piece of savage animalism; and it argues little artistic reception on the part of those concerned in this aimless copying, that no better rôle could be found for it. The only grace of the photograph in question is the fine way the light falls on Mr. Shaw's flanks. There are other nudes in this show: but none is so naked and unashamed. Two back-views of men with bowed heads, who sink towards "The Gloomy Portal," we may now regard as displaying a very pink of shrinking modesty. The portal is gloomy enough, but we fail to find in it any suggestion of poetical intent, and we think the whole affair utterly misses the mark. It is by Herr, or Monsieur, Paul Pichier, of Vienna ("Wien, Austria," in the catalogue, with delightful inconsequence, has it). Mr. William A. Stewart has two nude subjects, which are more or less successful, according to one's feelings about these things. For our own part, we are a little tired of the languishing or folded-up varieties of skins that look as though they were black-leaded. "The sorrow that is of Man and Endureth for Ever" is the cumbersome title of Mr. Stewart's crumpled-up figure, who appears to be balanced upon a globe of such dimensions that the slightest shove would slide him off and finish his sorrows for ever. (Poor Watts, and his Hope!) Mr. Stewart's other work is "Ex Umbra." It is a good

try, highly creditable; but photography does not lend itself to high-falutin' allegory treated realistically. Such a title as "The New Model" has been expediently chosen by Herr Heinrich Kühn for one of his two nude studies, in order to justify the embarrassing shyness found generally in all photographers' nudes, but particularly in this. The only thing that can save such essays from a lurking twang of naughtiness is a rightdown frank treatment, such as the ancient Greek adopted. We should not see nakedness in a truly artistic nude. Miss Adelaide Hanscom has done commendably in this respect. There is more than mere nudity in her "Nude Study." But of all the efforts that rely upon bodily beauty, there is, in our opinion, none here to beat Mr. Cavendish Morton's "Fantasia." We admit that in many respects it is showy, and, as indeed it claims to be, fantastic. It is nude in intent; although the paint, or "tights," in which the female harlequin is clothed might win an evasion of the law. But where she scores over the shame-crushed, face-averted undressed ladies of these haunts is in her conscious pride of the beauty of her own lithe form, strained and quivering with physical energy; and the firm sweeping lines that practised activity induces. Proud of herself, as she should be, she is proud of our pleasure in her, and confirms our estimate of her gracefulness by looking down upon us with a radiant smile that a half-mask only makes the more tantalisingly irresistible.

[The remainder of our notice must stand over until next week.]

### THE PRESS ON "LE PENSEUR."

Mr. A. L. Coburn's picture, "Le Penseur," having drawn forth a good deal of comment in the Press, we may quote a few extracts as showing the views entertained of the picture as a work of art, although opinions are less generally expressed on this topic than on the motives of "G. B. S." The "Chronicle" wrongs Mr. Coburn in attributing the possession of a wife to him.

The "Daily Chronicle" says:—Celebrities in the nude may, therefore, become a fashion. It has been a vogue before in oils, so why not with the camera? The lens may be made to show as much discretion as the painter's brush. Many artists, thinkers, and authors have sat to Mr. Alvin Langdon Coburn, who is a young American with a genius for impressionistic studies by the camera. He commands his own fees for a sitting, and is autocratic on the posing of his subjects. He has a wife who shows in the Salon some studies which reveal a sense of mystic beauty. And he has an individuality which is accentuated by the wearing of a straight brimmed silk hat.

Reviewing the Salon in a later issue, the "Chronicle" says:—There is at least one photograph which has already made itself very much talked about—by reason of what one hopes to be only a chance resemblance to a certain public man with no clothes on. If it were intentional it would have been a piece of bad taste, of which it is uncharitable to suspect the photographer.

The "Manchester Guardian's" London correspondent writes:—The "sensation" of the show is Mr. Coburn's "Le Penseur," which seems to wear the head of Mr. G. B. Shaw. A nude Napoleon, they say, was sculpt by Canova, but I can recall no other precedent.

The "Yorkshire Daily Observer" says:—The sensation of the show is a picture by Mr. Coburn entitled "Le Penseur"—a nude figure in the pose of Rodin's famous statue of the same title. If Mr.

Coburn's "Thinker" is not Mr. Bernard Shaw, the likeness is remarkable, and the critics have with one consent agreed that it is the original "Superman," with nothing between him and his Maker. Mr. Shaw stood sponsor for Mr. Coburn when he first came to this country, and a portrait of him was one of the most striking works in the artist's own exhibition. The new work, though it is occasionally some natural amusement, is not unworthy either of the artist or his model.

Whether (with Rodin's statue of the same title in his mind) Mr. Shaw posed for this work or not the result, as manifested by Mr. Coburn with the camera, is a picture of strength and subtlety.—"Evening Standard and St. James's Gazette."

The "Standard," writing of No. 130, says:—Here we have a portrait (*horrescimus referentes*) of Mr. Bernard Shaw. We are diffident in making this assertion, because Mr. Coburn or Mr. Shaw may say that it is not true. Short of proceeding to identification by fingerprints, however, we are prepared to affirm that the original of this portrait is Mr. Shaw. The picture is called "Le Penseur," and is quite like M. Rodin's famous statue. Mr. Shaw has sat for what Trilby called the *ensemble*, and in doing so he has made good his claim to seriousness for ever. M. Rodin, in a very noble way, showed that thought is a kind of physical effort; a kind of athletics—we have known that ever since Jacob wrestled with the angel—and represented his thinker as a man of Herculean strength, with ridged and knotted muscles. Mr. Shaw is less muscular, but as he is stripped for the purpose of thinking, we are left with very much the same impression. His head is held on his hand. He is going through an effort. At least that, seriously, is our impression; but you never can tell. All Mr. Coburn's work is excellent.

THE prize-winners in the Tabloid "metol-quinol" competition have been announced by Messrs. Burroughs, Wellcome, as follows:—1st (£5 5s.), F. W. Beken, Blenheim House, Cowes, Isle of Wight; 2nd (£3 3s.), Edward R. Bull, 53, Bovill Road, Forest Hill, S.E.; 3rd (£2 2s.), E. T. Holding, Innisfail, Marryat Road, Wimbledon; Three prizes of £1 1s., Herbert A. Game, 17, Pembridge Place, Bayswater, W.; William Maclean, 69, Clifton Park Avenue, Belfast; James Walker, Grange Mount, Cloughton, Birkenhead. In Wellcome's Photographic Exposure Record and Diary Competition the prizes go to William Maclean, 69, Clifton Park Avenue, Belfast, (£3 3s.); S. G. Kimber, Oakdene, Highfield, Southampton, (£2 2s.); E. S. Maples, The Lawn, Hopton, Mirfield, (£1 1s.). A similar competition for the best negatives produced with "Tabloid" metol-quinol developer closes November 26.

CLASSES in photography and process work will be held in the Acton and Chiswick Polytechnic, Bath Road, Bedford Park, W.

PHOTOGRAPHIC Classes at the Birkbeck College.—From the prospectus for the forthcoming session we see that, as hitherto, classes in photography will be held by Mr. E. Senior on Friday evenings. There is a lecture at 7.30, followed by an hour's practical class from 8 to 9.30. The fees for the first are 10s. from September to May, for the latter 8s. per term of twelve weeks.

LANCASHIRE and Cheshire Photographic Union.—Though dating from only January 1st this year, the Lancashire and Cheshire Photographic Union already embraces forty-one societies, nearly every large centre in the two counties being included. The president is Dr. C. Thurstan Holland, of Manchester, the hon. treasurer and business secretary being Mr. W. Tansley, of Liverpool, the founder and organiser of the union. The union's first combined outing was held recently, many representatives of societies as far north as Barrow-in-Furness, as far east as Accrington, and from various Cheshire towns, assembling at Liverpool.

## THE COST OF MANUFACTURING IN THE PHOTOGRAPHIC STUDIO.

An address bearing the above title was delivered by Mr. F. Dandas Todd before the meeting of the Convention of the Photographic Association of America, assembled at Niagara Falls. The figures given by the author are, of course, quite inapplicable to Great Britain but the method and suggestions of estimating cost of production are so eminently such as require to be seriously studied by those in business in this country that we here reprint a very large portion of Mr. Todd's address, withholding only those portions which, for personal and other reasons, were fitting only before the audience gathered at Niagara Falls.—Eds., B.J.P.

It may safely be said that the average photographer does not really know why he is in business. I know what I am talking about, because for several years I have frequently asked individual men why they were photographers and what they were in business for, and only once or twice have I been told by the man I spoke to that he was in business for the money he could make out of it. The others informed me that they became photographers because they liked it, or thought they would, because they drifted into it, and so on. The men I find who realise that they are in business for profit make a pretty fair living out of their calling, but the majority of professional photographers, not only in this country but the world over, in my estimation get very inadequate returns for their services. The reason is not far to seek. The big money to-day is to be found in the highly organised machine industries, where the various operations are largely mechanical. Combinations of capital eliminate competition and insure much higher dividends. The worker has seen the benefit of combination and in turn has increased his income to a more limited extent by the organisation of trades unions.

Professional photography in the world to-day occupies a rather unique position. A photographer's studio cannot be called a factory, nor in the strict sense of the word can it be called a profession, neither is it a business where a man buys and sells commodities. I can call it nothing but an occupation. Being outside of what an eminent professor calls the machine process, it can claim no scheme of organisation, and as a consequence each studio proprietor really blunders along with his affairs in a very haphazard manner. You will observe I am dealing very gently with the photographer as an individual; in fact, I am trying to show that his peculiar lack of business ability is due to the business he is in and not to any failings that are characteristic of the individual. His business up to now has called for antagonism between individuals, and he has suffered not only in his pocket but in his mind as a consequence. I am glad to see a feeling developing among many men that ultimately it will be found more profitable to co-operate than to compete, if it be possible to devise a workable plan.

### The Things Which Make up Cost of Production.

When a photographer estimates that a dozen cabinets cost him about a dollar he is thinking only of the material he will consume, and is not counting one cent for his own and employees' labour, nor for general expenses. But labour is a commodity which is bought and sold like plates, paper and card stock, and therefore must be considered as part of the cost. In the same way rent and taxes and such expenses must be paid for out of the business, must be earned by the business, and, therefore, must be calculated as a part of the cost of every individual print that is turned out of the photographer's studio. Recently, a plumber friend of mine told me that in figuring on a job he counted himself as being worth \$6 a day, then he added not only the cost of the material, the use of the wagon, the shop rent and similar expenses, but in addition he charged for the time he spent in estimating what he would do the job for. This is business sense and shows why plumbers make money.

I once asked an optician friend of mine how he arrived at the selling price of a pair of spectacles. The cost of the material is rather low, and he knew that I knew to a cent just what he paid for it. His answer was very brief: "I consider myself to be worth \$2,000 a year, and I allot a fair proportion of that sum upon every pair of spectacles that I sell to a customer." This was business sense.

An optician in a country town of less than 2,000 people, you will see, considers that his services to his community are worth \$2,000 a year. I wonder how much a photographer living in the same town would consider his services worth. I think he would be very modest and

be very thankful if he got a thousand. But I hold that at ninety per cent. of photographers in this country should earn with difficulty \$1,000 a year, but I am sorry to say I don't believe half of them earn that much. However, for the sake of argument I am going to assume that a photographer should get \$1,000 a year out of his business, and then I will proceed to take an average of what I see if we cannot find out the cost of manufacturing the print that this photographer sells.

### The Unpaid Wife.

Since all money that goes out of the business must be earned by the business we will have to consider every cent that is spent being an expense. Therefore, in figuring out cost, we will have to allow for the following items: First, and most important in my estimation, labour, which is supplied principally by the proprietor; comes material, rent, heat, taxes and insurance, postages, new apparatus, studio repairs and general waste. Last of all, hired labour if such be employed. Many photographers are assisted by their wives in the studio, and their services must not be considered as value nothing, but must be allowed for at regular market rates. Photographers seem to think that they are as badly off as preachers in this respect. You know that when a congregation hires a preacher at \$15 per week, if the congregation can scrape it together, this congregation ordinarily expects to get the services of the preacher's wife at the same time for nothing. I have always considered the preacher's wife being pretty rough on the preacher's wife, and rather small potatoes for the congregation, and you can just guess what I think of a neighbour who gets his wife's services in the studio day after day and figures them as worth nothing at all.

### Cost of Materials.

Having learned what expenses must be charged in estimating the cost of work, my next business will be to find some system where we can arrive at a fair approximation of the correct answer.

I have tackled this problem from two ends. In the first place I figured up the cost of all the material that enters into the making of a dozen cabinets in an ordinary studio. Here it is:

Four plates and developer.....	\$0.31
Proofs .....	.08
Envelopes and circulars.....	.02
Retouching one negative.....	.35
Paper for fifteen prints.....	.23
Toning chemicals.....	.10
Mounts for thirteen prints.....	.25
Tissue enclosures.....	.05
Total .....	\$1.40

If we deduct the cost of retouching the material used costs \$1.40 and I wish to draw your attention particularly to the fact that allowance is here made for re-sittings and only for a small waste of material, both of which cost a great deal more than the average photographer ever suspects. About ten years ago many of you remember that I tackled this very same problem, and at that time I found the cost of the material used in a dozen cabinets amounted to 60 cents. This means an increase of cost of 66 per cent. At first blush this increase is startling, and I find it is due to more plates being used for each sitter, more expensive toning chemicals, more expensive mounts, and in the use of enclosures for the finished prints.

### Expense for Labour, Rent, &c.

The cost of material you will thus see is a fluctuating expense and depends practically on the amount of business done. If there are orders for pictures then there will be no expense incurred for material. It is different, however, with the other expenses such as rent, salaries

which must be met day by day whether sitters come or not, if the photographer is to stay in business. I have had much correspondence with many photographers for nearly a year trying to discover what these constant or overhead expenses really amount to, but it is very difficult to secure exact figures. Even when I had found them, then came the problem how to apportion them among the various departments. For instance, the studio may be roughly divided into reception room, operating room, and printing room, and in order to secure a fair estimate of the cost of each department we must charge against them a fair proportion of the rent, heat, taxes, repairs, salaries, etc. To make matters more complicated, in the majority of studios an assistant rarely gives his services to only one department. The printer may also be the retoucher, or he may assist the operator, while the latter and the reception room lady divide the retouching between them. To unravel such a complicated problem one would require to get a statement from a rather large establishment where each assistant is confined to only one kind of work, and from such figures one could arrive at the data on a percentage basis. I will give you what figures I have secured, and then show you the conclusions I have arrived at, and then it will be for you to say whether or not my estimates are approximately correct.

Out of all the figures provided me by various photographers, I have compiled the following schedule of overhead expenses for an ordinary gallery employing a printer and having the retouching done outside.

Rent .....	\$250.00
Heat .....	50.00
Taxes and insurance.....	15.00
Postage .....	35.00
New accessories, studio repairs, and general waste...	250.00
Assistant .....	500.00
Owner's salary.....	1,000.00
Total .....	\$2,100.00

Now don't you see that every day in the week, including Sundays, whether sitters come in or not, this photographer has got to find \$6.00. If it has not come in over the desk that day he has got to dig into his pockets and find some cash that came in the day before or the week before, but find it he must if he wants to stay in business. If he has only one sitter at \$3.00 his dozen pictures that day cost him \$6.00 plus material and retouching, or \$7.14 in all. If he had five sitters at \$3.00 his pictures in all cost him \$7.00 for material and retouching, and \$6.00 for general expenses, or a total of \$13.00. Total receipts being \$15.00, he would have a profitable day's business, but I am afraid the surplus, \$2.00, might be swallowed up next day if it rained, so we must judge photography by the year. Having got some figures to go upon we can now do a little calculation as to how many sitters must patronise the gallery to make it a paying proposition. It all depends on the price. Some men offer cabinets at \$3.00 per dozen, and we find that at this price at least 1,300 sittings must be made, thus :

Receipts, 1,300 at \$3.00.....	\$3,900.00
Overhead expenses.....	\$2,100.00
1,300 at \$1.40.....	1,820.00
Total .....	\$5,920.00

At \$4.00 a dozen, eight hundred sittings will be enough, at \$5.00 about 650, at \$2.50 there must be two thousand sittings, and I am informed that more help and more space would be needed with more than two thousand sittings, so the limit, I think, has been reached when we consider cabinets at \$2.50 per dozen. Right here I want to point out that it is evident that there is a dead loss in the ordinary gallery in making a cheap line of cabinets at \$2.00 or even \$2.50 a dozen.

The Photographer's Public,

I have shown how many sitters must patronise a photographer at various prices in order that he make an income of \$1,000 a year. But is it possible to get a sufficient number of patrons to enter the average gallery? To me that is a most important question, yet I find it absolutely neglected. Let us see the possibilities. Photographers are fairly numerous in this country; in fact, there is generally one to every 3,500 or 4,000 people. Such evidence as I can secure indicates that only about 15 per cent. of the population are photographed in

any one year, or, in other words, the average photographer makes from 600 to 700 sittings annually. I have discussed the question with all grades of photographers, with men who get \$3.00 a dozen to those who get \$15.00 a dozen, and find the result is generally the same.

Here let me give figures from a country photographer doing all his own work except retouching.

Total cash received.....	\$2,188.76
Total stock used.....	\$768.72
General expenses, including retouching.....	518.93
	1,197.65
Net income of owner.....	\$991.11

He made 450 sittings at from \$2 to \$10 per dozen. The cost of material per dozen was \$1.40, including retouching it was \$1.85. As his income was a fair one in my estimation his cabinets evidently cost him \$4.85 per dozen. His cheap work was clearly made at a loss. A very important point arises here. Any photographer who is making only a fair living out of his business can readily see that his work costs him just what he gets for it; if he makes more than \$1,000 per year it is costing him less than he gets for it, but if his income is less than \$1,000 a year, then his work costs him more than he gets for it. I am still assuming \$1,000 a year as a fair income for the average photographer.

Many men tell me that they have figured out that if they could increase the number of sitters to a certain amount per day they could make money at a certain price. For instance, one man said that with 20 sitters a day he could make big money at \$2 per dozen. He was in a town of 35,000, with only seven photographers, so he had a chance to try the idea. At the end of three months he found he could not draw 20 sitters a day by any kind of scheme, and wanted to sell out on account of his health. I suspected the seat of his ailment lay largely in his pocket.

A Business with Three Assistants.

One very successful photographer employing three assistants gave me the following figures :—

Rent .....	\$780.00
Heat and light.....	250.00
Taxes .....	75.00
Insurance .....	100.00
New accessories and repairs.....	150.00
Postage .....	75.00
Help .....	2,800.00
General waste.....	300.00
Repairs .....	100.00
Material .....	2,415.00
Total .....	\$7,045.00
Own salary.....	1,500.00
	\$8,545.00

He made 2,300 sittings, so a dozen cabinets cost him \$3.71, while the material alone cost \$1.05 a dozen, which you will notice is the amount to a cent that I estimated at the beginning of my talk.

It seems to me that this photographer's figures really give us the minimum cost of a dozen cabinets. He gets \$5.00 a dozen, so you see he is not using high-priced material nor paying extravagant salaries. I fancy few men could run their business more economically so until I get more light I am going to assume that \$3.71 per dozen is about as cheap as it is possible for a dozen cabinets to be made.

Distribution of Expense Charges.

I have told you that I have tried very hard to get figures that would enable me to apportion the expense to the different departments of a studio. We all know there is the reception room, skylight and printing room. Given the expenses of each department one should be able to learn just what percentage should be allotted to each. I will try what I can do, but cannot guarantee more than an approximation, simply because no one can give me the necessary figures.

The reception room is the finest part of the studio. It is generally large, well furnished, and in the best location. I think myself at

least half the rent of the premises should be charged against this one room, while most of the repairs and general waste are incurred right here. The other half of rent, taxes and similar expenses may be evenly divided between the operating and printing rooms. I have had to guess at the division of the salary among the employees. I allow the reception lady almost \$12 a week, the printer \$20. I assume the retoucher devotes part of his time to assisting the operator, so give him a salary of \$25 a week, and charge one-third against the operating-room, and the balance for retouching. I allowed, you will remember, \$1,500 a year to the owner. I charge the operating room with \$1,000 of this, and divide the balance among the other departments for superintendence.

This table shows my results:—

	Reception Room.	Oper. Room.	One Retouching.	Printing Room.	Total.
	Dols.	Dols.	Dols.	Dols.	Dols.
Rent.....	380-00	195-00		195-00	780-00
Heat and Light .....	125-00	62-50		62-50	250-00
Taxes.....	37-50	18-75		18-75	75-00
Insurance .....	50-00	25-00		25-00	100-00
New Accessories and Repairs ..	75-00	37-50		37-50	150-00
Postage .....	75-00				75-00
Help .....	600-00	400-00	800-00	1,000-00	2,800-00
General Waste .....	150-00	75-00		75-00	300-00
Repairs on Studio .....	50-00	25-00		25-00	100-00
Material .....	45-00	73-00		1,656-00	2,415-00
Management .....	250-00	1,000-00	125-00	125-00	1,500-00
	1,518 50	2,551 75	925-00	3,219 75	8,545 00
Cost of Each Sitting .....	0 8037	1 09	4021	1 8999	
Total, 2,300 .....		1 10	40	1 40	3 71
Percentage .....	21 8	29 6	10 8	37 7	99 9

If the retoucher is considered as helping the printer in his spare time instead of the operator, we will have to deduct 18 cents from the one department and charge against the other. This would reduce the expense in the operating room to 92 cents and make the cost of a dozen prints \$1.56, that is, 13 cents each. The actual result is this:

Each sitting seemingly costs the reception room 81 cents, the operating room \$1.10, the retouching room 40 cents, and the printing \$1.40. Now this is on the basis of cabinets costing \$3.71 per dozen if they cost more each department must be charged more, then I have worked out the percentage figures thus:—Reception room, 21.8; operating room, 29.6; retouching, 10.8; printing, 37.7.

These figures, I think, are rather interesting, and I will supplement by the percentage figures that refer to material. Total material is a little over 28 per cent., plates and development little over 8 per cent., paper, mounts, and toning chemicals, 16 per cent.; stationery expenses, 2 per cent.

A resitting takes up the time of the reception lady as well as of the operator, so both must be charged; therefore a resitting costs \$1.92. A duplicate order costs \$1.40 in the printing room, but I add the reception room lady's time the total cost will be at least \$3. Remember all these figures are on a specially low basis, and, therefore, most of you here must figure at least 10 to 20 per cent. higher.

Let me conclude by pointing to the immensity of the photographic business. There are in this country 16,000 photographers in business as near as I can learn. We have seen that the stock for sitting costs a little over one dollar, so the photographers of the country buy every year about ten million dollars' worth of plates, paper, mounts, and chemicals. That is an enormous business, and no wonder that many photographers spend much time figuring how to save a little on their stock bills. And yet I often think that energy is being wasted in a wrong channel, for even if they save 10 per cent. it would amount to the average man to less than several dollars a year. I am of opinion that the real point for the photographer to worry over is how to get a higher selling price. I honestly of opinion that a fair price for a dozen cabinets of ordinary style should be at least \$6.00, and it is up to you as business men to endeavour to get it. I am afraid you will never get it fighting it out, and sooner or later you will have to organise as all other occupations are doing, and strive to co-operate rather than to compete.

F. DUNDAS TORR

## FOREIGN NOTES AND NEWS.

### Sulphites and Bisulphites.

Now that the use of bisulphite of soda has been prominently brought to the front by the recent work of MM. Lumiere and Seyewetz, the following note by M. Lecorney may be useful:—

To convert sulphite into bisulphite by the aid of sulphuric acid the formula is

53 ccs. or 98 gm.      252 gms.      208 gms.      142 gms.

The conversion of the bisulphite into sulphite is expressed by

208 gms.      286 gms.      252 gms.

The following table shows the various transformations taking as base one or other of these substances.

The 40 per cent. solution of bisulphite corresponds to the commercial solution:—

Sodium Bisulphite Cryst.		Sodium Carbonate Cryst.		Sodium Sulphite Anhydrous.	Sulphuric Acid Pure.	
Crystals.	40% Sol.	Crystals.	20% Sol.		Ccs.	Drops.
208 gms.	520 ccs.	286 gms.	1430 ccs.	252 gms.	53 ccs.	1378
1	2.5	1.38	6.87	1.21	0.255	6
0.40	1.0	0.55	2.74	0.46	0.101	3
0.73	1.82	1.0	5.67	0.88	0.184	5
0.15	0.36	0.20	1.0	0.13	0.037	1
0.22	0.26	1.13	5.0	1.0	0.21	5
3.92	9.81	5.40	27.0	4.75	1.0	26
0.16	0.38	0.21	1.03	0.13	0.04	1

This table shows, for example, that if to 1 gm. of anhydrous sulphite, 0.21 ccs. of pure sulphuric acid be added, 0.82 gm. crystallised bisulphite or 2.06 ccs. of bisulphite will be obtained; convert this into sulphite 1.13 gm. of crystallised sodium carbonate 5.67 ccs. of a 20 per cent. solution are required.

Other acids may be used; thus for 100 gms. of anhydrous sulphite may be used

Hydrochloric acid	...	24.13 ccs. or 28.96 gms.
Citric acid	...	55.55 gms.
Acetic acid	...	44.9 ccs.

with which 82.54 gms. of bisulphite will be obtained.

The above are the theoretical quantities for absolutely pure chemicals. Allowances must of course be made if they are not pure. It must not be forgotten too, that the secondary products, such as the sulphate, chloride, citrate, &c. are formed according to the acid used.

FRAUD on a Carlisle Photographer.—At Carlisle Police Court last week, Sophia Begley, no fixed address, was charged with obtaining £2 10s. by false pretences from Mr. F. W. Tassell, Devonshire Street. The Chief Constable said prisoner called upon Mr. Tassell on October 28th last year and offered to sell him two water-colour pictures which she said were painted by De Wint, the celebrated artist, whose name was upon them. She gave the name of Mrs. Jefferson, and said she had had the pictures for many years. Mr. Tassell gave her £2 10s. for the pictures, but when he sent them away to be examined it was found that they were forgeries. The magistrates sent her to prison for one month in the second division.

Fig. 20.—Showing conventional form of dots, depth, diameter, and side action of 110-line engravings, Figs. 9, 10, and 11, from Table F. The clear spaces are not diagonal, consequently the relation of depth to clear space is greater than if the diagonal distance was used.

The element of uncertainty found in etching practice is largely

Fig. 21.

Fig. 22.

Fig. 23.

The numbers indicate the lines per inch. They are ordinary etches. It will be noticed how much nearer to white the coarsest screen runs in comparison to the finest lines, because the smallest black dots (•) bears a smaller relation to unit area and the ratio of the two unit areas to each other is in favour of the coarser lines. The data relating to these special test engravings are given in Table K.

Fig. 24.—Etching rates at 110 lines per inch, from Tables A and F, and Figures 2, 9, 10 and 11.

due to a lack of precautions, which, if taken, would avoid the "making over" of many pieces of work, give the etcher greater control and confidence over, and in, his medium, and thereby eliminate the unsatisfactory quibbling between the clerical and practical departments of the business. What the operator and etcher require to know is that specific causes under like conditions produce identical results. No amount of specious reasoning will alter this inexorable law, and the sooner its scope is learned the better for the trade and all concerned.

It now remains to more exhaustively investigate the law or second or periodic acceleration, and it is hoped to also present numerous photo-microscopic enlargements produced in a novel manner so as to admit of easy and definite comparisons. The relation of half-tones and wood engraving printing qualities will also be made the subject of further treatment, as well as the co-relation of mechanical engraving methods as applied to specialised uses. The relation of specific gravity of the etching medium to temperature and the effect of etching rates will also be taken up in due time. N. S. AMSTUTZ.

**BURNLEY Camera Club Exhibition.**—The prospectus of the forthcoming exhibition is now published, and is obtainable from the secretary, Mr. Fred Whitaker, Mechanics' Institute, Burnley. The judges will be Alex. Keighley and Frank M. Sutcliffe, who will award eleven solid silver vases and thirteen electro-plate goblets. The Burnley Camera Club have made a point in past years of purchasing pictures for their permanent collection, and the practice is one which will doubtless be repeated at the forthcoming show, entries for which should arrive not later than November 10, 1906, the exhibits themselves following on November 13.

**THE Leeds Photographic Society** has made arrangements for a series of one-man shows in the Municipal Art Galleries during the winter months, commencing October 1. The first of the series will be a selection from the works of Mr. Alex. Keighley, and the promises of support from well-known workers leave little doubt that the high standard of the first exhibits will be maintained.

**The Photochrom Company.**—We are asked to announce that the successor of Mr. E. L. White, whose retirement from the managing directorship of the Photochrom Company we announced last week, is Mr. F. M. Lambert.

## THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

We give in "Ex Cathedra" a few impressions of the fifty-first exhibition of the Royal Photographic Society, which opened yesterday at the New Gallery, Regent Street. A detailed review of the photographs must be deferred to next week. Meanwhile we may congratulate the Selecting and Hanging Committee on the result of their labours. The west room (devoted to the pictorial section) never looked brighter than it does this year, and the scheme of decoration is one which contains its own recommendation in the fact that it sets off the frames and their contents, but that it is difficult to recollect of what it is itself composed.

In the technical section the only medal goes to Mr. C. Welborne Piper for a set of models of light-pencils showing various effects of aberration. Colour photography is not represented so largely as was anticipated, but the pictorial sections and technical sections both include one or two examples of three-colour photographic printing.

The Selecting and Hanging Committee (pictorial section) are: W. R. Bland; Furley Lewis; G. A. Storey, A.R.A.; W. T. Greatbatch; J. C. S. Mummery, A.R.I.B.A.; and B. Gay Wilkinson.

The Judges and Selecting Committee (scientific and technical section) are: T. Bolas, F.I.C., F.C.S.; Douglas English, B.A.; Sir J. W. Swan, M.A., F.R.S.; Chapman Jones, F.I.C., F.C.S.; E. Sanger Shepherd; E. J. Wall; and Major-General J. Waterhouse, I.A.

We may remind our readers of the lecture arrangements at the New Gallery during the next seven days: To-morrow (Saturday) Mr. W. Farren lectures on "Wild-bird Life with the Camera." On Monday the lecturer is Mr. Henry W. Bennett, and his subject

"Five Centuries of Church Building in England." Thursday's lecture will be "Homeward Across the World—Burma, India, Egypt, and Italy," by Mr. A. H. Dunning.

The members of the society dined together at the Holborn Restaurant on Tuesday evening. Owing to the indisposition of the president (Major-General Waterhouse), Mr. J. C. S. Mummery occupied the chair. About sixty covers were laid, among those present being Messrs. J. H. Sinclair, H. C. Zerffi, S. H. Fry, H. Snowden Ward, C. F. Inston, H. Holcroft, E. T. Butler, Leslie Clift, George E. Brown, C. E. K. Mees, Arthur Payne, James Brown, F. J. Mortimer, Dr. Lindsay Johnson, C. H. Oakden, T. K. Grant, P. L. Thornton, E. D. Hoppé, Charles Houghton, and others.

There were only two toasts down on the programme—that of the "Royal Photographic Society" and the "Visitors." In proposing the "Royal Photographic Society," Mr. Mummery expressed the regret which he with many others felt at the absence through indisposition of General Waterhouse. He congratulated the society on the exhibition which had been brought together in the New Gallery, and he regretted that the other members of the Selecting and Hanging Committee were not present that evening to receive the thanks of the members. Mr. John H. Gear, in proposing the toast of the "Visitors," coupled with it the name of Mr. Alvin Langdon Coburn, who, in briefly responding, said that he was satisfied that the present rivalry of the two London exhibitions constituted the best possible conditions. An excellent musical and dramatic programme was rendered by Messrs. Churcher and Strugnell.

The conversazione of the society was held at the New Gallery, Regent Street, on Wednesday evening. A large gathering of members and their friends filled the spacious rooms.

### FORTHCOMING EXHIBITIONS.

September 14 to October 27: The Photographic Salon.—Sec., Reginald Craigie, 5a, Pall Mall East, London, S.W.

September 20 to October 27: Royal Photographic Society.—Sec., J. McIntosh, 66, Russell Square, Bloomsbury, London, W.C.

October 6 to 13: Bristol Photographic Club.—Sec., J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

October 17 to 20: Rotherham Photographic Society.—Sec., H. C. Hemmingway, Tooker Road, Rotherham.

October 24 to November 14.—West of England Exhibition (Photographic Section). Entries close October 1. Sec., A. D. Breeze, 41, Union Street, Plymouth.

October 31: Watford Camera Club.—Sec., E. H. Jackson, 100, High Street, Watford.

October 31–November 1.—Watford Camera Club. Last day for entries, October 25. Secretary, Edwin H. Jackson, 5, Lower Derby Road, Watford.

November 7 to 8: Bedford Camera Club.—Sec., W. H. Hodge, 58, Beaconsfield Street, Bedford.

November 7–10.—Motherwell Camera Club. Entries close October 25. Exhibits must be sent by November 2. Secretary, Jas. Dunlop, Myrtlebank, Motherwell, N.B.

November 7 to 10: Hackney Photographic Society.—Sec., Walter Selie, 70, Paragon Road, Hackney.

November 14 to 17: Rugby Photographic Society.—Sec., R. H. Myers, 13 Bridget Street, Rugby.

November 15 to 27: Burnley Camera Club. Entries close November 10.—Sec., Fred Whitaker, Mechanics' Institution, Burnley.

November 16 to 21: Southsea Amateur Photographic Society.—Hon. Sec., F. S. Hoyte, "Lismore," Stafford Road, Southsea.

November 20: Sefton Park Photographic Society.—Sec., A. W. Parr, 34, London Grove, Liverpool, S.

November 27 to 30: Hove Camera Club.—Sec., W. H. Bone, 32, Sackville Road, Hove.

December 6 to 8: South Manchester Photographic Society. Entries close November 21.—Secs., J. H. Haywood and M. W. Thompson, 43, Lapwing Lane, West Didsbury.

December 11 to 15: Southampton Camera Club.—Sec., S. G. Kimber, "Oakdene," Highfield, Southampton.

1907.

February 13–15.—Northern Tasmanian Camera Club. Last day for entries, December 31, 1906. Secretary, F. Styant-Browne, 112, Brisbane Street, Launceston, Tasmania.

February 23 to March 2: Birmingham Photographic Society.—Sec., Lewis Lloyd, Norwich Union Chambers, Birmingham.

February 11 to 14: Cripplegate Photographic Society.—Sec., J. B. Parnham, "Chagford," Old Church Road, Chingford.

February 12 to 23: Sheffield Photographic Society.—Sec., J. W. Wright, 62, Vale Road, Sheffield.

February 22 to March 4: Norwich and District Photographic Society.—Sec., J. T. Tanner, The Lodge, Norwich.

March 14 to 23: Leicester Photographic Society.—Sec., W. Murray, 60, Melton Road, Leicester.

April 29 to May 14: Photographic Society of Ireland.—Sec., R. Benson, 35, Molesworth Street, Dublin.

WILLIAM H. MACHEN, a photographic plate-maker, giving his address as Courtney Street, Kennington, was charged at the West London Court with causing to be received by Henry Carvell Beaven, photogravure printer, of Shaftesbury Road, Hammersmith, a letter threatening to murder him. Prisoner stated that he was not well when he wrote the letter. The magistrate remanded him.

PHOTOGRAPHING the Drowned.—At the inquest last week on an unknown man found on Clacton beach, the coroner, Dr. Harrison, said he had discontinued having photographs taken of drowned persons, as they were not reliable for identification.

THE prospectus of the exhibition of the Bristol Photographic Club has now been issued, and is obtainable from Mr. J. S. Guthrie, 23, Berkeley Square, Clifton, Bristol.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received from September 3 to September 8:—

**COLOUR PHOTOGRAPHY.**—No. 19,652. Selective taking screens for colour photography at one operation. Clare Livingstone Finlay, 22, Marchmont Street, Russell Square, London, W.C.

**PRINTING FRAMES.**—No. 19,943. Improved printing frame. Thomas Richard Proctor and Houghtons, Limited, 88, High Holborn, London, W.C.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FLEXIBLE DARK SLIDES.**—No. 19,165, 1905. The invention relates to dark slides, in which the shutter—like a paper bag in form—envelopes the support of the photographic sensitive surface or its carrier, but with its open end being received into a collar so as to be closed, and in whose production flexible materials are employed, either for the shutter (English patent No. 1,109, of 1901), for the collar, or for both. In dark slides of this

Fig. 1.

kind the open end of the shutter or of the collar or both may present slight irregularities, rendering the introduction of the shutter into the collar difficult when closing the dark slide after loading or after exposure. In the present invention an insertion piece is fitted to the collar. Figs. 1 and 2 show a double dark slide of the suggested pattern. The two supports,  $a^1 a^2$ ,

Fig. 2.

of the sensitive surfaces are accommodated in a carrier,  $b$ , the main body of the dark slide, which is turned back at one end to form the collar,  $c$ . From the opposite end, after housing the supports of the sensitive surfaces, the shutter,  $d$ , has been pushed home over the carrier,  $b$ , and into the collar,  $c$ . To assure the entry of the shutter into the collar, the insertion piece,  $e$ , whose two tongues are connected together to form an embrasure, has been inserted over the carrier,  $b$ , and into the collar,  $c$ . After the dark slide has been closed, the insertion piece is withdrawn from it. It is, perhaps, more suitable to give the insertion piece,  $e$ , a permanent position by fixing it upon a standard and to introduce, before closing the dark slide with the shutter, the carrier between the tongues of the insertion piece until the collar surrounds them. Richard Schüttauf, Carl-Zeiss-Strasse, Jena, Germany.

**CINEMATOGRAPHS.**—No. 12,072, 1906. The invention consists in

the eccentric connection of two shafts, a main shaft and secondary shaft, by means of arms, cranks, or, generally speaking, by any radii, one of which, belonging to the main shaft which may rotate uniformly, presses the other radius, fixed upon the secondary shaft; the ratio of the lengths of the radii increasing and diminishing alternately during the rotation of the secondary shaft receiving a velocity which is also continuous, but variable, which it communicates to a connecting rod or similar part serving to displace the cinematograph band directly by means of claws or by the intermediary of a supplementary device of any appropriate kind, interposed between the connecting rod and the band, in such a manner that the connecting rod traverses the path more speedily in one direction than in the opposite direction. Casimir de Proszynski, Rue André Dumont, Liege, France.

**PRINTING FROM RELIEF PRINTS.**—No. 996, 1906. This invention relates to a method of printing from surfaces wherein the picture stands in relief, and is based on the fact that if the parts of the surface which are in relief and the parts not in relief are of different material, a suitable printing medium may be affected differently by these two parts, so that when, after application of the medium, an imprint is made, only one of the parts is printed because the medium has disappeared from or been altered by, the other part. For instance, the parts in relief and those not in relief may affect differently the speed of evaporation of the printing medium. The material of which the relief consists may hinder the evaporation or otherwise retain the printing medium, while the latter evaporates from the parts not in relief. Thus, a gelatine relief on a glass plate may be used as the printing surface. If this is uniformly treated with a suitable printing medium, during the evaporation of the latter a residue will be retained by the gelatine and can be imprinted on a suitable surface to form a picture since the parts not in relief will not have retained any printing medium, and therefore will not be imprinted. When the differential effect of the relief and the non-relief is upon the rate of evaporation, the printing medium may be any suitable substance which is sufficiently volatile. A solution of hydrogen peroxide in ether or the like, formaldehyde, ammonia, formic acid, acetic acid may be mentioned as suitable. In what follows the printing process will be described as it may be conducted with an ethereal solution of hydrogen peroxide: The picture is a gelatine relief, prepared photographically or otherwise, which for simplicity's sake may be supposed to be a line picture which may rest on glass or on some other support from the surface of which hydrogen peroxide evaporates completely, the parts of the support between the lines of the picture being bare. If such a picture be flooded with an ethereal solution of hydrogen peroxide, the gelatine will absorb the hydrogen peroxide and retain it. The gelatine absorbs hydrogen peroxide in proportion to its mass, and if one waits until the peroxide has evaporated from the glass and then imprints the picture on a surface of gelatine paper, satin paper, or textile fabric, the lines will be reproduced on the surface in imprinted hydrogen peroxide, and the latent image thus produced may be developed in known manner. If the picture is not merely a line picture but possesses half-tones, the different parts of it absorb the peroxide in proportion to their depth of tone so that the half-tones are reproduced in the imprinted picture. To prepare a printing surface of this kind, a picture wherein the material in relief is of a non-catalytic nature, such as a chromated gelatine relief, like a developed pigment picture, is treated in known manner, so that the relief is transferred to a surface which is capable of uniformly decomposing the printing medium catalytically. Where the latter is hydrogen peroxide, printing must be effected immediately after the printing surface has been treated with the peroxide, because the catalytic surface will speedily decompose the hydrogen peroxide which diffuses through the material in relief. A. G. Bloxam, for the Neue Photographische Gesellschaft, Siemens Strasse, Steglitz, Berlin.

**PNEUMATIC RELEASE.**—No. 17,127, 1905. The object of the invention is to provide a uniform air compression for use with a time value, permitting of longer exposures. On a cylinder,  $a$ , of metal or other suitable material, we form at one end a nozzle,

b, for attaching a connecting tube, c, the opposite end being provided with a screwed cap, d, containing a central opening to receive a piston-rod, e, which projects slightly through and is furnished with a knob or head, f, for the purpose hereinafter described. To the end of the rod, e, that lies within the cylinder is fixed a piston, g, of any suitable form or material which shall be airtight in its passage. In the normal position the said piston is pressed into contact with the nozzle end of

Fig. 1.

the cylinder by means of a spiral spring, h, which at the other extremity abuts against the inner surface of the screwed cap, d. In this position the aforesaid rod is driven home so that the head, f, only projects beyond the orifice in the screwed cap. To prepare the device for use the rod is withdrawn against the tension of the spring to its full extent, as shown by dotted lines, by means of the head, f, when a spring operated detent, i (more clearly shown in Fig. 2), pivotted on the screwed cap, engages in an annular channel, j, formed at a suitable position on the piston-rod, to retain it in the set position until ready for expo-

Fig. 2.

sure. The cup leather flange, k (which we at present adopt), on the piston, g, allows of this part of the process being readily effected, as it offers very slight resistance to the displacement of the contained air when moving in the backward direction, but forms airtight contact with the interior surface of cylinder, when forced by the spring, h, in the opposite direction, by the aid of an endless spiral spring, q, held in an annular channel of the piston boss, r. The act of pressing the detent away from the piston-rod, by means of the turned-down lip, i<sup>1</sup>, allows the piston spring, h, to come into play, thus driving the air contained in cylinder through the connecting tube, c, and inflating the teat as explained in the foregoing in respect to the compression of a rubber ball. By this plan a constant volume of air at a uniform pressure is brought into use at each time of operating, and when a time valve is used, uniform conditions and results are ensured. Houghtons, Limited, 88 and 89, High Holborn, London, W.C., and Alfred Sidney Spratt, Tudor Road, Hackney, London, N.E.

An Umbrella Photograph Album.—According to the "Drapers' Record" the umbrella handle is to be turned to new uses. Many new designs are to appear on the market, and one striking creation in silver is a handle in the form of an onion top, with spring lid opening at each side, which contains six miniature photographs.

## New Books.

"Les Procédés d'Art en Photographie." By R. Demachy and C. Puyo. Paris: The "Photo-Club." 12 francs.

This handsome volume, announced some months ago in our pages as to appear under the auspices of the Photo-Club de Paris, has now been issued. It is of quarto (11 x 9 inches) size, and a beautiful production, both as regards its typography and the inclusion of forty-one supplemental plates, each one of which is appropriately mounted on a matt paper and illustrates some part or other of the authors' writing. The aim of the book is clearly conveyed by the title. It is to give an account of those processes involved in the making of the negative and the print which can be of service to the photographer whose interest in his subject is that of a pictorialist. M. Demachy and Major Puyo, true artists that they are, do not seek to talk art, or art principles, or to impart to the photographer a sense of composition, of chiaroscuro, or the other elements which make the artist. These, we believe they would say, are not to be taught, and to talk and write about them is so much waste of time. M. Demachy, as we have read his writings, has persistently set his face against making easy the acquirement by the pictorially-minded photographer of any ready-made form or fashion of art. He has had plenty to say of tools and processes and media, but he has earned our respect by holding aloof from any temptation to create followers, or to establish a type of pictorial photography along particular lines. And we are glad to see that he, with M. Puyo, does not swerve from this course in the present volume. Save for the introductory chapter on "Interpretation," wherein the authors explain the licence they would claim for photography as a means of pictorial expression, the volume is devoted to the technics of the subject. And the subject matter is exactly what we should expect from MM. Demachy and Puyo; which we take to be the same thing as saying that it is precisely that which all those who have seen the works of these leaders of French pictorial photography will desire to study. In other words, the authors write only of those processes which for the past ten years they have used in their own artistic work with almost daily regularity. Needless to say, gum-bichromate figures largely in the list of processes; indeed, with the exception of platinotype, which the authors dismiss altogether—too summarily we think, all the methods described are those for obtaining a pigment image. The majority of those are the *depuillement* processes—there is no English equivalent for the French word used to signify the "development" of a picture by washing away the superfluous pigment—but the authors come at the close to processes such as Mr. Rawlins' oil, in which the control is obtained by adding pigment, not by washing it away. Altogether, the chapters include: Gum bichromate, single, multiple, and multi-colour, commercial gum papers—Artigue, Fresson, "B.F. Rapide," and "Aristique"—other commercial pigment papers—Farinaud, Hochheimer (chromatype), Deux Epées, and Auto-pastel. We have also the authors' experience of gelatine-ozotype—M. Demachy is punctilious in specifying colloids—gum-ozotype; and, lastly, the oil process of Mr. Rawlins. We have nothing but the highest praise for the volume as a whole. Though the text is French, the illustrations should reward any purchaser of it who wishes to study the works of MM. Demachy and Puyo, by whom most of the reproductions are supplied. In a few cases the interest of these is enhanced by the reproduction on the same page of a print direct from the negative, showing the direction in which control in the gum print or on the negative has been undertaken.

A third edition of Dr. Eder's great treatise on photography, the well-known "Ausführliches Handbuch der Photographie," is just commencing its appearance from the publishing house of W. Knapp, Halle, a/S., Germany. Hitherto separate parts of the "Handbuch" have always been obtainable, but a further concession is being made in the issue of the third edition by the publication of the complete book in fortnightly parts, each at the price of one mark (1s.). The first of these, "Lieferungen," as the parts are called, commences the first volume, viz., that dealing with the history of photography. It runs to seventy pages, and contains a supplemental plate of the

panoramic Daguerreotype taken of Paris by Lerebours and Secretan in 1850. We congratulate the publishers on thus placing the volume at the disposal of those of limited means. The sum of sixpence a week for this classic work ought certainly not be so large as to prevent anyone able to read its contents from purchasing it.

THE *Annuaire Général et International de la Photographie* has to be welcomed once more on the appearance of its fifteenth issue. Under the editorship of M. Roger Aubry, it preserves its accustomed arrangement and exhibits no signs of diminished bulk. Following a very French frontispiece, there is a "revue" illustrated with photographs from the studio of M. Paul Boyer in Paris. The review of technical progress during the past year occupies a large part of the volume, and is followed by some contributions from French writers, among which is a posthumous article by M. Vidal on methods of pinatype printing. The usual collection of tables and formulæ and a very full directory of the members of French photographic societies conclude the volume, which is published by MM. Plon-Nourrit and Co., 8, Rue Garancière, Paris, at the price of 5fr. Mention should be made of the numerous illustrations in the text, and as supplements they include the work of MM. Demachy, Puyo, Dubreuil, and other leading exponents of pictorial photography in France.

## New Apparatus, &c.

"Solar" and "Combinar" Anastigmats. Made by C. Reichert, Bennongasse 24/26, Vienna, Austria.

We have received from the firm of C. Reichert, Vienna, two new objectives for examination, the "Combinar" and the "Solar." The "Combinar" is described as a rapid universal objective, adapted for all kinds of work. It is a symmetrical anastigmatic doublet of focal length, 180 mms. (7in.), and aperture of  $f/6.3$ , made up of two similar anastigmat single lenses, each of 312 mm. ( $12\frac{1}{2}$ in.) focal length and aperture  $f/12.5$ . It is claimed that these single lenses will cover plates the length of which is equal to the focal length. The doublet appears to cover a half-plate most excellently at full aperture, and to give a very flat image field with only a quite slight negligible trace of astigmatism. The single lenses behave equally well on the same plate, and the whole combination strikes us as a most useful one for a half-plate camera, while it is obviously serviceable as a wide angle lens for much larger work. The "Solar" is an anastigmat of 180 mm. (7in.) focal length and aperture  $f/5.8$ , made up of two similar single combinations that can be used at small apertures for landscape work. These single lenses are not corrected for astigmatism, as is the case in the "Combinar." The doublet covers a half-plate well, but though its astigmatic corrections are good they do not seem to be of quite the same high order as in the "Combinar." The trace of astigmatism left shows the cross-shaped focus of a point of light, which fact denotes that the astigmatism is nearly pure, and practically the only "spherical" defect left. The apertures of these lenses are marked on the unfamiliar Goetz system, with numbers that represent exposure ratios. This marking by itself seems to us to be inadvisable, as the average purchaser does not understand it. The series of apertures marked 6, 12, 24, etc., corresponds very approximately with the usual series  $f/8$ ,  $f/11$ ,  $f/16$ , etc., while those marked 4, 8, 16 correspond with  $f/6.3$ ,  $f/9$ ,  $f/12.5$ . The "Combinar" would be improved by the addition of a second scale, to be used with the single combinations, and in both cases reference numbers should be employed.

LIVERPOOL Amateur Photographic Association.—The concluding exhibition of the series which has been a feature of the Association's activity during the few months opens on Monday next, in the shape of seventy-one photographs by F. K. Glazebrook. It remains open at Eberle Street until September 25.

MESSRS. SANGERS, the London agents of the well-known Walls-grove photographic series of chemicals, are now removed to large building in Euston Road, W.C.

## New Materials.

"Takis" Self-developing Paper. Sold by the Lumière N.A. Comp. 4, Bloomsbury Street, New Oxford Street, London, W.C.

In this new paper the Lumière firm have produced a distinct novelty in the materials at the disposal of the photographer. Apparently the paper is a variety of P.O.P., with the substances for development of a faintly printed image incorporated in the emulsion. Water serves to dissolve these chemicals and bring about the intensity of the print. At any rate, the behaviour of the print during the operations suggests a form of physical development, such as we have been familiar with in its application to P.O.P. The tones obtained after development in the water are warm in colour, but are tonable in the combined toning and fixing bath, without previous treatment in the platinum bath. The tones obtained in this way are quite satisfactory and equal to what can be obtained on ordinary printing-out paper. The instructions for the use of the paper are as follows:—The paper is exposed in the printing frame to daylight until the image is clearly visible. The exposure may vary within wide limits. The print may be quite faint, the image being only barely visible, but is better to expose a little more fully, say for about five minutes. The print is placed in a dish containing about  $3\frac{1}{2}$  ozs. of clean water for a print 7 x 5 inches. After it has been wetted about half of the water is thrown away and the development continued with the remainder. The print shows gains in intensity, and when it attains sufficient strength is washed for a short time in clean water and then transferred either to platinum toning bath, for black tones, or direct to the combined bath, for purplish black tones. Simple fixation of the developed print in hypo will leave it with a good sepia tone. In range of gradation the paper, as we have found it, is certainly of very good quality. We may not be convinced that the form of manipulation necessitated by the paper is that which is destined to become popular, but the new paper is a step further in the direction of substituting the organised skill of the manufacturer for the manipulation of the user, and it is a step which appears to us to have been taken with the care and experience which we associate with the great firm of Lyons.

## CATALOGUES AND TRADE NOTICES.

THE Imperial Dry-Plate Company, Limited, send us a leaflet explaining the use of the "Imperial" orthochrome light filters, not supplied to work with the two brands of "Imperial" orthochromatic plates. The leaflet, we presume, will be sent to anyone who applies for it.

A CATALOGUE of optical appliances employed in photo-mechanics work has been issued by the firm of Carl Zeiss, Jena. It describes the lenses of the Zeiss manufacture specially adapted for process work—viz., the Series V. Protar, Series VIII. Apochromat Tessar, and Apochromat Planar. The firm is also a maker of high-class reversing prisms and mirrors and focussing magnifiers, and can undertake the complete optical equipment of the photo-engraver's establishment. The list, which should certainly be of service to the process man, showing him the design of the Zeiss instruments, may be obtained from the firm's London house in Margaret Street, Regent Street, W.

KEIGHLEY PHOTOGRAPHIC ASSOCIATION.—The annual meeting of the Keighley and District Photographic Association was held on September 11, at the Keighley Technical Institute, Mr. W. Robertshaw (president) in the chair. Mr. N. Barrett submitted the seventeenth annual report, which recorded a successful year, the membership having increased from 76 to 84, and the balance in hand from £3 0s. 5½d. to £5 1s. 4d., in spite of considerable special expenditure. Mr. Robertshaw was re-elected president, Mr. Walter Mitchell hon. treasurer, Messrs. F. Mahony and H. E. Haggas co-secretaries, and Mr. Cyril Smith librarian.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
	Chelsea and District Photo. Soc.	Outing to Wimbledon Common.
	Aberdeen Photo. Art Club.....	Outing to Milltimber.
	Aberdeen Photographic Assn.	Outing to Bishop's Loch.
	Coventry Photo. Club.	Outing to Brandon.
	Bowes Pk. and Dis. Ph. Soc.	Outing to the Inns of Court.
	North Middlesex Photo. Soc. ....	Outing to Hampstead Heath.
	Luton Camera Club .....	"Carbon, Platinotype, and Page-Croft Pigment Paper."
	South London Photo. Society ..	"A Developing Competition." C. Churchill, F.R.P.S.
	Southampton Camera Club .....	"Gedona." Messrs. J. J. Griffin & Sons.
	Hackney Photographic Society	"Street Photography." Wm. Rawlings.
	Manchester Amat. Photo. Soc.	"Lantern Slide Making." Mr. J. D. Berwick.
	Leeds Camera Club.....	Lectures by Members.
	North Middlesex Photo. Soc. ....	"Promide Toning," also Lantern Show.
	London and Prov. Photo. Assn.	"J. H. Avery." "Madeira Up to Date." A. L. Henderson.

### PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, September 14. Present:—Messrs. F. A. Bridge, Alfred Ellis, S.H. Fry, Martin Jacolette, A. Mackie, Edgar Scamell, Lang Sims, and Wollons Willson. Mr. Martin Jacolette, president, was in the chair. Correspondence was read between the Hon. Secretary and the Hon. Secretary of the Artistic Copyright Society in reference to a proposed conference between representatives of the two organisations on the subject of the treatment of photographers' copyright in the Bill to be brought before Parliament by the A.C.S.

A letter was read from the Secretary of the Actors' Association thanking the Committee of the P.P.A. for the consideration given to the questions put by the Actors' Association on the subject of the treatment of members of their profession with regard to copyright in photographs and for the replies thereto. The Hon. Secretary made a report of the business of the Association and its progress during the recess. The fourth number of the "P.P.A. Circular" had been issued to members, and had given rise to some correspondence with members, particularly with regard to certain trading firms, about whom information had been asked. The exhibition of members' work, arranged to be held at the office of THE BRITISH JOURNAL OF PHOTOGRAPHY, had received a sufficient number of entries to ensure an interesting exhibition. The account with the Fine Art and General Insurance Company showed that the company had to pay the Association about £9 for commission, being 5 per cent. on the premiums of the special policies issued to members. New members had been admitted to the number of 53 since the issue of the "Handbook," practically three and a half months. The applications for advice, etc., had been of about the usual number for the period embraced, but were of a more serious nature than usual, and showed that members were beginning to appreciate the usefulness of taking an independent opinion upon matters where their interests might lead to a prejudiced view of the case. Three cases of disputed accounts had been dealt with. In one a satisfactory settlement was arranged. In another, one of the parties refused to negotiate; and in the third case a writ was issued before the Association had opportunity to intervene. In this case a settlement might have been arranged if the member had brought the case to the notice of the Hon. Secretary earlier. Four cases of infringement of members' copyright had been dealt with. In all of them a reasonable amount of compensation had been obtained without recourse to law proceedings.

The question of an allowance to the Hon. Secretary for clerical assistance, etc., was then discussed and an arrangement come to.

## Commercial & Legal Intelligence.

PHOTOGRAPHIC Materials, Ltd. (Westminster).—Issue on 21st August of a £184 15s. 4d. 6 per cent. debenture, part of a series created 24th April, 1906, to secure £25,000, charged on the plant, machinery and stock at Scot's Bridge Mill, Rickmansworth, certain patents and copyrights, and the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £2,800.

THE Canvassing Business.—At the City of London Court last week, Mr. J. T. Jacobs, 80, Cranbrook Street, Bethnal Green, sued Messrs. A. and G. Taylor, photographers, 153, Regent Street, for the return of 7s., money which he had paid to them. The plaintiff said that a collector from the defendants called upon him, and he agreed to have one large photograph and six small ones. For them he was to pay 35s. by instalments of one shilling per week. He had paid seven instalments, and then the collector did not call again. As the defendants had neglected to carry out the terms of the arrangement, he asked for the return of his money. The defendants' representative said that the plaintiff had not called for a sitting. They were ready to give it to him at any time. They would then execute the order, and send a collector weekly for the instalments. The Assistant Registrar adjourned the case for the photograph to be taken.

TWELVE Months for Mr. John Burns's Champion.—At the Clerkenwell Sessions last week, George Lawrence, labourer, pleaded guilty to stealing a handbag and umbrella from the photographic studio of Guy Rawlings, at Chichester House, Chancery Lane. The prisoner is the man who obtained some notoriety as Mr. John Burns's champion, having claimed to have interfered on behalf of the right hon. gentleman when he visited a lodging house in Drury Lane recently. A police constable produced the list of the prisoner's previous convictions (a terrible record), dating back forty-three years, and including one term of five and three terms of ten years' penal servitude for a variety of offences. Lawrence was ordered twelve months' hard labour.

## News and Notes.

"LE PENSEUR."—It is rumoured, no doubt erroneously, that a quotation should have accompanied the picture of "Le Penseur" in the Photographic Salon; but that it was inadvertently omitted from the catalogue. The figure is represented as carrying out the philosophic command, "Know Thyself," and the quotation ran:—"All the world's a stage. What am I? Am I a 'super' man, a ballet man, or just a 'walking gentleman'? I'm not quite Shaw." It has been hinted also that the model employed for this work has thought of doing a statuery "turn" at the London Pavilion with La Milo, but is a little dubious of passing the censorship of Mr. Stead so triumphantly as that lady did. It is more likely therefore that he will take the advice of Miss Corelli as to the advisability of using the photograph as a frontispiece to a new book of plays now in preparation—that is, when he is assured of his position in copy-right matters.

INSTRUCTION in Optics.—The prospectus of classes at the Northampton Institute reaches us from the secretary of that institution, who kindly draws our attention to the lectures and laboratory practice in optics in the department presided over by Mr. S. D. Chalmers, M.A. The course of Wednesday evening lectures includes seven evenings devoted to photographic apparatus, according to the following syllabus:—Construction of Cameras. Details of adjustments; simple landscape lenses; importance of stop as regards illumination and correction of defects. Nature of defects, their influence on image; symmetrical objectives, modern forms. Effect of light on photographic plates—orthochromatic plates and screens; requirements of colour photography, the testing of photographic lenses. Stops, shutters, construction, and testing. Telephoto-

tography. Stereoscopic apparatus. In the laboratory arrangements are provided for proving and studying the fundamental laws of optics, and for making the simpler scientific and commercial optical tests. Photometers of various kinds are available, and optical benches enabling the focal lengths of mirrors and of spherical or cylindrical lenses to be tested by various methods. The students are also practically instructed in testing plane and curved surfaces by the spherometer and optical methods, in centering lenses and lens combinations. They also have opportunities of making simple tests on telescopes, photographic lenses, projection lanterns, and microscopes. The senior optical laboratory has been specially equipped for the testing of photographic apparatus, telescopes and microscopes, as well as materials and portions of optical apparatus. Its equipment includes special apparatus for testing telescope objectives and eye-pieces, the Beck Photographic Lens-testing bench; a Zeiss microscope with apochromatic and other objectives; the Abbe spectrometer. Special apparatus for measurement of curvatures and refractive index of lenses. Facilities are also given for the testing of surveying instruments, a 5-inch Transit theodolite and a 14-inch level being available. A well-fitted dark room is annexed to this laboratory.

**A CINEMATOGRAF Fire.**—About noon on Monday last the residents of the Haymarket were alarmed by a serious fire in an off street, known as James Street, on the premises of the Cinematograph Film Company, Limited. The building is numbered 15b, and in addition to the company already mentioned there were, as tenants, the Crown Art Co., Ltd. The house was comprised of two storeys, and was wedged in between much larger buildings, with contents of an inflammable description. The narrowness of the street caused those on the opposite side, as well as the occupants in the adjoining houses, to become greatly alarmed. The fire was caused by the ignition of a film, and, according to an eye-witness, "it flew through the house fully ablaze, as though it had been shot out of a gun." Within a short space of time the premises were on fire from the ground floor to the roof. The building, despite all efforts, was completely gutted, but the damage is covered by insurance. A telephone standard situate on the roof of the building, and bearing a large number of wires, was so damaged as to seriously interfere with telephone communications. A rough estimate of the damage is set down at £10,000.

**FREAK Photograph.**—The "Dublin Evening Herald" reproduces a freak photograph, in which a man is represented standing by the side of a table on which rests his own head, his trunk being seen in the background. The author of the photograph writes:—"The picture is the result of a triple exposure on the same negative. To take the photograph I fastened a strip of black cloth to the rear of the studio for a background, and placed a stand in front of it. Then I lowered the camera until its top was level with the stand of the table. Getting the stand in focus, I had an assistant kneel back of the table, with his chin resting on the surface. Then I placed a piece of black cloth, to correspond with the background, between him and the legs at the back of the stand. This cloth was fastened to the stand to keep the body from being seen through the legs of the table, and corresponds with the background, also of black cloth. Thus I made ready for my first exposure. Next I had my assistant, whose head is seen on the table, stand at the left, and I covered his head with a black handkerchief, exactly corresponding in colour with the black background. Thus the face was hidden, and the man's body appeared with the head cut off. So the second exposure was made. Then I had the assistant remove his coat and stand to the right of the table with a knife in his hand, to make it appear that he had cut off his own head. This completed the third exposure, all on one plate.

**THE Photographic Convention.**—The local committee making the arrangements in connection with the Photographic Convention of the United Kingdom, to be held next summer at Hereford, took place at Clarence House, West Street, on Friday last. Mr. Alfred Watkins presided. The hon. secretary (Mr. W. T. Carless), having explained in detail in reference to the question of finances, it was decided that a subscription list be formed, and that a circular be drawn up with that object. It was suggested that, though there

had been a great demand for hotel accommodation at Hereford summer, there would probably be no difficulty in arranging accommodation at the hotels and boarding-houses for the visit to the convention. The question of excursions during the week referred to and discussed at some length, boating, driving, and way outings having been suggested. Mr. Watkin (president), Carless, Mr. W. Cecil Gethen, Mr. A. C. Edwards, jun.; and W. P. Pritchard were appointed a sub-committee to make the necessary inquiries, etc., and report to a subsequent meeting of committee. It was decided to ask Mr. Wilfrid Groom to allow name to be added to the committee.

**HACKNEY Exhibition.**—The annual exhibition of the Hackney Society will be held on Nov. 7, 8, 9, and 10, at the King's Hall, Hackney Baths, London, N.E. There will be six open classes, awards of silver and bronze plaques. The judges are Messrs. Henry W. Bennett, W. Greatbatch, and Furlay Lewis. Exhibitions will be collected without charge from the Salon and Royal Photographic Society's Exhibition. Conveyance from Hackney is offered by the Southern Exhibitions to all exhibits entered for South Hove, and Southampton. Entry forms for these exhibitions may be obtained from Mr. F. S. Hoyte, "Lismore," Stafford Road, Southsea. All exhibits must be sent to the King's Hall, Hackney Baths, London, N.E., not earlier than Friday, November 2, or later than Monday, November 5. Mr. Walter Selfe, the secretary, of Paragon Road, Hackney, will send the prospectus.

**MUNICIPAL Photographs.**—Once again the vexed question of providing a set of photographic views of Cardiff and the surrounding district came before the Parliamentary committee on Tuesday last week, and it is a striking commentary on a public body's way of negotiating in a little matter of this kind that, although competition was opened about three months ago, the city council just as far off the attainment of the object in view as when the thing was first mooted. There was a curious blunder committed the initial stages of the "enterprise" by asking Cardiff photographers to compete for a small prize of £5, which would not be enough cover the expense attached to the production of a really good set, say nothing of recompense for the work and trouble involved. The prize of £5 was awarded to a certain photographer, but his set was not brought into use, so that nothing was gained by the award of this first prize of £5 and a second prize of £3. The next development was a recommendation that a sum of £25 should be given Mr. W. Jenkins for a set of photographic views which were submitted to a meeting of the Parliamentary committee about a month ago, and which were considered to be of excellent quality and great artistic value. The committee recommended the council to pay Mr. Jenkins this sum of money, but the council considered the professional photographers in the city were not properly treated, and that they should be given the opportunity of competing for this sum of £25, and they passed a resolution accordingly. In the interval between the meeting of the Parliamentary committee and the council meeting, however, Mr. Jenkins had proceeded with the preparation of his set of views on the strength of the Parliamentary committee's recommendation. And now arises the question, "What is to pay Mr. Jenkins for the work he has already put in?" This was the main point in a letter read from Mr. Jenkins at another meeting of the Parliamentary committee. Another letter, signed by Messrs. J. O. Long, A. Freke, H. J. B. Wills, and A. Lawrenson (Messrs. Taylors), in which they sought the right to compete for this prize of £25, was read. Mr. Lewis Morgan suggested, as a way out of the difficulty, that they should find out how far Mr. Jenkins had gone, and to what extent he should be compensated. The majority, however, were in favour of inviting Mr. Jenkins to compete for the £25, and that is how the matter stands.

**WHERE Cameras are Dangerous.**—The American Consul at Trieste warns visitors to Montenegro that the authorities of that country have issued an order that no aliens, single or in groups, carrying weapons will be allowed to travel in the principality without danger of being arrested and transported to Cetinje. Foreigners carrying cameras without a written permission will be prosecuted, even if they take only snapshots of the scenery.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

### COLOUR-PRINTING IN ENGLAND AND ABROAD.

To the Editors.

Gentlemen,—It is impossible to feel hurt or vexed with the mild and courteous dissent expressed by Mr. Whatsname in a communication to which you have justly granted the treatment of an article. I neither do I think his dissent damaging to the position I took in my original article. On the contrary, my one and constant ejaculation, when reading Mr. Whatsname's article, was "Exactly." Mr. Whatsname says, "All that Mr. Tilney says has been said many times before about France." I am not an idiot, then, in the etymological meaning of the word. Mr. Whatsname further says, "It is quite true that competent art direction is desirable in photo-engraving," a noble sentiment which embodies my whole point. After admitting what has been said many times about France and begging for the inclusion of Germany in the argument, Mr. Whatsname proceeds to excuse England on the score of speed of delivery and "rush"; but I did not say that England could not find an excuse. So long as the malefaction is admitted I do not bother about the excuse—another name for cause. I state the lamentable fact. The point is, can English firms turn out work as good as the best foreign firms in even double the time the latter would take?

Mr. Whatsname says further, "Does he (that's me) think the Germans are not experimenting with filters (I think they are, for all they're worth), as well as using the 'art' direction (I claimed that they were), because if so, he is mistaken; though I can assure him they are still doing more fine-etching than we are in England, and, if their results excel, it is due to the patient care with which this part of the work is executed." (Exactly!)

It would be tedious to go through all Mr. Whatsname's points, but I could do so and prove how he plays into my hands every time. Mr. Whatsname dilates upon the "unfortunate" habit of money-making; of the turning out of work for greater profit; dares me to testify to the better temperament of the German for colour reproduction; and finally drops into grave social questions, such as ill-timacy, where I confess I am out of my depth.

Mr. Whatsname's conclusions is a desire to "meet" me; but once, for me, he has neither a local habitation nor a name, I do not know how I can oblige him, apart from the fact that I am unused either to firearms or to jiu-jitsu.—Yours, etc.,  
F. C. TILNEY.

### THE WORD "AEROGRAPH."

To the Editors.

Gentlemen,—I was very much surprised on looking down "The Birmingham Daily Mail" to notice a paragraph on Marconi's invention headed "Aerography." It is the first time I have heard of wireless telegraphy being called aerography. It would be interesting to know what is the correct term for the photographer "aerograph."—Yours truly,  
J. SQUIRES.

The Regent Studios, 125, Gt. Lister Street, Birmingham.  
September 1, 1906.

[The word "aerograph" for wireless telegraphy is, of course, a bad misnomer, for the operations are in no way dependent on the air, and can hardly be called writing. Its inappropriateness was pointed out at a lecture delivered at the Society of Arts last winter, by Mr. A. L. Burdick, and if our correspondent will turn to our issue of January 19 of this year, he will see a reference to the very point which he raises.—Eds., B.J.P.]

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

Wilkinson & Co., 1, Royal Arcade, The Walk, Norwich. Five Photographs of Edwards' Sand Pits, Norwich.

W. A. Culeshaw, 119, High Street, West, Sunderland. Photograph of the Sunderland Association Football Team, Season 1906-7.

Bell & Peterson, Humbert Street, Jarrow-on-Tyne, Durham. Photograph of the Jarrow Congo Cycling Club Fire Brigade.

W. E. Dixon, 131, Midland Road, Bedford. Photograph of the American Ambassador with the Harvard Crew.

A. E. Kirk, Claremont Drive, Timperley, Cheshire. Photograph of an Old Print of Old Victoria Street, Manchester.

STEREO TRANSPARENCY PLATE.—The European Blair Company have ceased to manufacture their "Premier" Lantern Plate (rapid chloride). Is there any similar plate in the market stereo size (6½ x 3½)? If so, please say where it can be obtained.—J. J. M. P.

B. J. Edwards and Co.'s "Krystal," John J. Griffin and Sons' "Gaslight," and Paget Prize Plate Co.'s "Gravura" are all made in this size. So also are the Blue Label lantern plates of Austin Edwards.

STUDIO QUERY.—Will you kindly favour me by answering the following? I have taken a shop; the size of yard is only 25ft. by 11ft., so I am thinking of having a 12 x 9 studio erected, as I may have trouble with the surveyor to get one any larger; so, as it is small, kindly let me know how best to have it lighted so as to get as much light as possible. Would only require to operate from one end. Could I have glass start 2ft. from door, and carry on to 4ft. from end, so as to give me 6ft. of glaze?—PYRO.

The studio will be exceedingly short for any kind of portraiture, and we should have thought it would scarcely be worth building for professional purposes. We would suggest that you have a door in the end of the studio, so that the camera at times can be put out in the yard so as to get greater distance between lens and sitter. As we have no idea of the aspect of the studio, or its surroundings, we cannot advise about the lighting. But we should say have 7ft. of glass instead of 6ft., as it is easy in so small a place to stop out any light that may not be required.

BACKGROUNDS, ETC.—I should esteem it a favour if you would kindly answer the following: 1. Name and address of firm who supply canvas of sufficient size to make backgrounds. 2. Are aniline dyes the right thing to use for tinting photographs (such as the Leviathan colour outfit).—A. E. G.

1. What is generally used for backgrounds is unbleached sheeting. It may be had at the large upholstery warehouses or drapers' establishments up to eight feet wide, if not wider.

2. Yes, they are largely used (see reply to "Miniature.") 3. The lens has not quite the rapidity of a portrait lens, but it is quite rapid enough, and an excellent lens for portraiture and groups.

FLASHLIGHT.—I have noticed in your answers to correspondents

that the amount of powder you advise as necessary in flashlight work is in all cases a third (and sometimes less) than I have been in the habit of using. Will you kindly advise me where I am wrong? I use Ross Homocentric and Ross Zeiss protars at  $f/11$ , and — plates and weak pyro-soda developer, and yet for a group of eighty people arranged in group formation I have to use 3oz. of — powder, and then the resulting negative is under-exposed. I always use a short focus lens, so as to bring the light as near as possible to the objects being photographed. Will you kindly tell me: 1. Are there faster or more suitable plates than above? 2. Is there a more suitable developer? 3. Does flashlight powder become less actinic and more explosive with damp or age? 4. How to store the powder and keep it fresh?—FLASHLIGHT.

1. Certainly. Such brands as the Zenith or Monarch of the Ilford Company, the Flashlight of the Imperial Company, to name two only. 2. Pyro-ammonia would be better, or metol or rodinal. 3. Damp powder does not burn so quickly, and we should say that more must be used. The explosive properties would not be increased by damp, but rather decreased. If kept dry, age alone will not affect the powder within a reasonable time, say six months. 4. In a glass-stopped bottle. We do not think you will find much difference between the leading powders in this respect.

H. E. C.—Of course, the passage is a mistake, for "at an angle of 45 deg." These blunders of hurried writers in the lay Press are not infrequent.

EMPLOYMENT IN FRANCE.—I should like to get employment in a photographic studio in France. Can you advise me how to procure same? Also, can you tell me of a French trade journal? What is your opinion of the profession in that country? Also the usual salary.—IOAN.

Several publications (periodicals) can be used to find a situation, such as the "Photo Revue" (Ch. Mendel, 118, Rue d'Assas, Paris); "La Revue de Photographie" (44, Rue des Mathurins, Paris). As a rule, situations do not abound, and go generally to the fittest. There are, as in England, good, bad, and indifferent operators to be found, and the wages vary accordingly, from four or five pounds a month up to twenty; but we think this last figure very rare indeed. If you can correspond with a first class firm dealing with photographers, and can show good work, it would be better than advertising.

S. BARNARD.—The correct principle is to drive warm air through the cupboard, not to draw it. We have returned sketch with suggestion on back. Unless your shelves completely fill the cupboard, so that no air can pass except over the surface of plates, it will be sucked up the sides, and you will practically have stagnant air over the centre of the plates, and therefore unequal drying marks.

S. PORTER.—We are sorry we cannot say. Why not address a letter to the secretary of the Nottingham Camera Club?

A. N.—We have not the volume by us, but if we recollect rightly the dodge consists merely in giving two exposures, one on the bottle and one on the person, the same plate being used for both. Certainly, it will work.

A. T. (Walthamstow).—1. The photographs prove the difficulty of obtaining the eye fully open in the photograph. One of the prints seems fairly good, but the other is evidently not well defined. We think you would get better results on orthochromatic plates exposed through a screen. 2. It is possible you may register the postcard as a design, but if you cannot do so, it will be best to obtain provisional protection at the Patent Office. In the former case you will apply personally at Stationers' Hall, Ludgate Hill, E.C. In the latter you had better write to the Comptroller, 25, Southampton Buildings, for particulars of the cost, etc., of the patent.

BIO-BIO.—We cannot say. You had better write to one or two of the French and German photographic papers, the addresses of which you will see in the "Almanac."

UNEXECUTED ORDER.—Shall be obliged if you will inform me on the following matter: Some time ago (six months) I gave a man a picture to paint in oils. It was promised in four days, but we have not received it up to to-day; it has been promised

every day for months past, but we cannot get it, and lost trade, through it. Have I any ground for action damages.—STUDIO.

You can sue the man in the county court for the value of the picture you sent to be coloured. If you sued for damages should doubt if you would receive much, if anything.

VARIOUS.—I am an old wet-plate man, so you must excuse apparent childishness of my queries. 1. I want to take m and postcards by gaslight, and my space is limited. What lens shall I require ( $f/4$ ), and what the shortest dist between lens and sitter for three-quarter length? 2. Can advise me as to best lamp and number of burners? 3. Where to get accessories, such as motor-cars, railway carriage, etc.—W. R. KING.

1. If you wish to take full-size postcard portraits, you require a lens of about 8 $\frac{1}{2}$  in. focus; this will, for a quarter length portrait, require a distance of somewhere 11 ft. between camera and sitter. For midgets, of course, If you do not want to fill the postcard, a 6 in. focus lens suffice, and that will require a shorter distance. 2. The Company, 205, Oxford Street, supply a gas-lamp for purpose; write them for a prospectus. 3. Such houses Marion's, Fallowfield's, and Houghton's.

COPYING.—I have a photograph of two heads in a circle 2 $\frac{1}{2}$  in diameter which I want to enlarge to 9 $\frac{1}{2}$  inches diameter. I have got a good negative by daylight, but the paper n show terribly, and the girls look as if they had got me. I have tried copying with two 100-c.p. electric incandescent lamps (one on each side), but get the same effect. Is there way of getting over this other than re-touching, which is almost impossible? The original is printed on self-toned paper.—BEE.

If you had sent us the print we would have advised better. We should advise you to get as even an illumination as possible, and expose more fully than you have done, so the plate develops quickly. If this is ineffective, we can suggest making a print from the enlarged negative, and have this worked up.

COLOURED MINIATURES.—I shall feel extremely obliged if you give me any information as to how enclosed miniature is produced and coloured. (1) What paper are they printed on? (2) Is coloured? If you look through photograph against a strong light you will see the colouring is simply a daub, which I think must be put on from the back. The method of attaching celluloid I find is stated in Journal of the 31st ult.—MINIATURE.

We published a short article on the subject on April 6. The prints are made on gelatine P.O.P. (2) The colours aniline dyes, and are applied to the front of the print with brush. Three only are used—red, blue, and yellow—and effects obtained by admixture, either beforehand, as red and yellow to form the flesh tint, or whilst being applied.

SUBSCRIBER.—(1) Too cheap. (2) Certainly, the lady's face is somewhat blurred. We should wish for rather better definition of the lady's face, but we think the lack of distinct features might be remedied by retouching. We are of your opinion that such low-priced work is bad enough to leave alone.

\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received in to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The Cameron Exhibition at the "B.J." Offices closes to-morrow week, October 6.

The following Thursday, October 11, a "Single Picture" Exhibition, by members of the Professional Photographers' Association, will open. It will be the first exhibition held in this country at which professional photographers voluntarily combine to show each other the class of work being turned out from their studios.

Keeping properties of developers. Mr. Henry W. Bennett contests our views expressed some weeks ago that sulphite in the same solution with carbonate speedily spoils. (P. 765.) We discuss our own and Mr. Bennett's views. (P. 762.)

Messrs. C. E. K. Mees and S. H. Wratten have determined the properties of the new yellow dye for light-filters. (P. 765.)

Herr E. Valenta has examined a number of printing colours for permanence. (P. 770.)

A Tokio correspondent points out the need of a swinging lens on reflex cameras intended for press photography. (P. 777.)

Royal Photographic Society's Exhibition. A review of the pictorial section appears on page 767.

Lenses for studio work. An article for the beginner in professional photography appears on page 764.

A recent estimate places the money spent in pictorial postcards annually in the United Kingdom at £3,600,000. (P. 762.)

We give the arithmetical rule for finding the proper separation for stereoscopic negatives. (P. 761.)

The photographic trade has fallen off somewhat in Germany, according to the latest returns. (P. 761.)

## EX CATHEDRA.

### Photographic Manufactures in Germany.

An interesting statement as to the present condition of the manufacturing trade in Germany is given by "Die Photographische Industrie," a German trade paper. From this it appears that five of the principal photographic paper manufacturers showed in 1905 a profit of £97,125, as against £108,435 in 1904, or a reduction of £11,310. Only one firm showed an increased profit—viz., £7,237. This shrinkage in profits is stated to be due to the cutting of prices. Three dry-plate makers show a profit of £14,011 in 1905, as against £15,652 in 1904, or a decrease of £1,641. The German trade is advised to push their manufactures more in export, and also to combine to reduce the price-cutting. The loss in the export trade is particularly noticeable, also in camera-making, though here the figures are somewhat incomplete. There is one feature which has been particularly noticeable during the past twelve months in the German photographic journals, and that is the energy with which some of our English plate and paper makers are pushing their wares there, and it should afford some gratification to our patriotic sense that British plates are able to find a market in the face of the German tariff.

### Rule for Mounting Stereoscopic Views.

Stereoscopic slides cannot give a true stereoscopic effect unless they are observed under the same conditions of convergency as those which prevailed when the exposures were made, and the true effect cannot be secured unless the views are mounted with the proper degree of separation and observed from the proper distance. If the two negatives are on one plate, as is usual in most cases, and are produced with lenses a known distance apart, it is quite easy to ascertain the proper mounting separation for the positives. The complete rule for a lenticular stereoscope is as follows:—Add the separation between the two lenses (centre to centre) to the distance separating the eyes of the observer, and then deduct the distance between any two corresponding points on the two negatives. The result is the proper separation of the same two points in the positive prints. If the points selected are distant points, their separation on the negatives will be equal to the lens separation, and the two distances will therefore cancel each other. It is then only necessary to mount the positives so that two corresponding distant points are separated by a distance equal to that between the eyes. If there are no distant points in the view the complete rule must be applied, and if all the objects are very near, it is especially important

that the rule should be strictly observed. If a prismatic stereoscope is to be used, the width of one prism should be added to the positive separation as found by the rule. This addition is exactly correct if the prisms are half-lenses properly centred in front of the eyes, and, though these conditions are seldom fulfilled, the correction is generally true enough for all practical purposes. With very near objects and widely separated lenses the proper separation for the positives is sometimes so small that the prints have to be trimmed down to absurdly small dimensions. Further, the negative images come very near the ends of the plate. To avoid these effects the separation of the lenses must be reduced, and the adjustment is best made by trial on the focussing screen, for if each of the two negative images is fairly well centred in its own half of the plate, a convenient mounting separation will generally be secured.

#### Postcards in 1905-6.

The recently issued report of the Postmaster-General for the official year which closed on the last day of March last records some interesting figures with regard to the transmission of postcards through the post. The number of postcards delivered in the United Kingdom during the above period was 800 million 300 thousand, an advance of fifty-five million on the previous year, or an increase of nine per cent. This figure works out to 18.5 postcards per individual per annum. Assuming, as has been estimated, that three-quarters of the postcards are of the picture variety, we obtain an idea of the present volume of the home trade in these articles. Those who predict that the postcard craze is on the wane will perhaps point to the fall in the increase this year. Three years ago, when the postcard business leapt into existence, the increase in the postal cards transmitted was 25.5 per cent.; the following year it was 19.7 per cent. Still, the 9 per cent. of this year is considerably above the average increase for the years previous to the introduction of the pictorial cards, and shows that the custom of sending these missives is still upon the increase. The constant new issue of cards proves that the trade is one which permits of stock being very rapidly disposed of, and there need be no pessimistic feelings as to a consumption which represents over £1,200,000 spent in postage alone. Assuming that the average price of cards sold is 1½d., the amount expended in the retail purchase of cards is £3,600,000.

#### The Use of Sulphite of Soda.

In an article on another page, Mr. Bennett criticises a note that appeared in our issue of June 15 upon the question of the keeping powers of soda sulphite in conjunction with an alkali. Unfortunately, he seems to have misunderstood our note, and, in consequence, his criticism is somewhat misdirected. We certainly said nothing about retardation of development due to the conversion of sulphite into sulphate, or did we suggest that sulphate would assist in the production of stain. On the contrary, we stated that effects produced could not be accounted for by the oxidation of the sulphite into the sulphate, which is a very stable compound. We doubt if the sulphate has any positive effect of consequence, and the only result of its addition to the developer that we are acquainted with is a lightening of the colour of the solution. Mr. Bennett has surely confused the issues. The sulphite is a restrainer, an excess will retard development to a most inconvenient extent, and hinder the attainment of density. If sulphite becomes partially oxidised to sulphate it exercises less restraint and also is less effective as a stain preventer, and these changes may lead to curiously deceptive results. If, for example, we have a pyro stock solution that is gradually losing its reducing power, and an alkali solution containing sulphite that is gradually losing its restraining power, the two in combination will for a long time apparently exercise the same power or rapidity of development while the staining properties will gradually increase. We have noted such effects repeatedly, and, further, in the course of our experiments, we have found that a saturated compound solution of sulphite and carbonate (only two months old) acted in precisely the same way as a fresh solution of carbonate alone. This amply proves that sulphite practically disappears in the alkaline solution after a fairly short time.

\* \* \*

#### Stainless Negatives.

Mr. Bennett's idea of a stainless negative evidently differs from ours. In the latter part of his article he refers to the composition of a developer not being favourable to the production of a black tone, which idea is just the one that we endeavoured to combat in our former note. The brown-coloured image he refers to is not a necessary consequence of using pyro which, with properly devised formulae, gives as black an image as metol or any of the new developers, and does so without the aid of an acid or any other special kind of fixing bath. Such images cannot well be obtained with formulae in which the sulphite and carbonate

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES.

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of

particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—The attention of advertisers is specially directed to the announcement that the entire edition of the ALMANAC (25,000 copies) will again be placed in the hands of dealers and the trade on December 1, and is to be well in advance of the Christmas publishing season. The co-operation of advertisers to that end will be esteemed by the publishers.

together, on account of the rapid deterioration of the sulphite, but they are very easily produced if the sulphite is not properly preserved. The whole secret of stain prevention is the presence in the developer at the time of use of a sufficient quantity of sulphite, and this condition is not secured if the sulphite deteriorates in the stock solutions. It has already been pointed out by Messrs. Lumière and Seyewetz that sulphite keeps better in conjunction with pyro than in solution, and our experiments have proved most conclusively that it deteriorates very rapidly in conjunction with an alkali. In these circumstances it is obvious that the pyro bottle is the proper place for the sulphite, and experiment shows that if this simple alteration is made in the formulae we obtain black images instead of brown ones. Also we find another effect. The sulphite not only prevents its stain-preventing properties, but also its restraining powers, hence such non-staining developers are slower in their action than the ordinary developers that give brown images. These latter developers, when used, consume much less sulphite than was put into them, and the rapid action, coupled with the brown stain, enables us to use weak developers containing two grains of pyro per ounce. If the stain is obviated and the sulphite retains its restraining power, four grains of pyro become necessary, but there is no loss from the economical point of view, for these non-staining developers can be used for many plates in succession. For example, we quite recently exposed twenty-four plates in one lot of developer, treated four plates at a time, and increasing the time of development by one minute for each successive batch. In the sixth batch the developer was cloudy, which is not that fresh is required, but up to that time it was perfectly clear and clean, and gave admirable results with no trace of stain in any instance.

\* \* \*

ervation  
pyro.

This is quite a separate matter from that of stain prevention, which is dependent on the preservation of the sulphite.

Mr. Bennett, we pinned our faith for many years to sodium metabisulphite, but we finally abandoned it on account of the waste of pyro involved. Occasionally we have experiences similar to Mr. Bennett's, but on the whole found it was quite unsafe to trust a solution that was more than three months or so old. Often we found half-bottles had almost completely lost all power of development; hence the beginning of our experiments. We have all tended to indicate, though not exactly to say, that free sulphurous acid is deleterious in some way or other, but not very clear. For several years past we have used a sulphuric acid preservative that has proved perfectly satisfactory in every way. This is simply sodium sulphite, rendered neutral to litmus by the addition of one quarter of an ounce of potassium metabisulphite, and this solution has proved to have two valuable properties. As a pyro preservative it does all we can wish, while as a sulphite preservative it keeps admirably. However stale it may be, it always makes a good amidol developer, and this is by no means a bad test for the preservation of sulphite. It should be observed that a pyro stock solution made with this preservative is not yellow, as described by Mr. Bennett. It turns yellow as it deteriorates (of course, no solution will keep for ever), but it will remain pink for many months. Our tests are fairly severe in respect of the qualities, as they involve exposure in half-filled glass flasks to strong diffused daylight, in a south-facing room for at least three months. Our previous tests with sodium metabisulphite were mild in comparison, as only dark blue solutions were used, and the solutions were kept most rigorously

ously in a dark cupboard and never exposed to anything but gaslight.

\* \* \*

#### A Non-Staining Pyro Developer.

The following is an example of a non-staining developer that we can recommend so far as our experiments have gone:—(a) Soda sulphite, 2 ozs.; potassium metabisulphite,  $\frac{1}{2}$  oz.; pyro of pyrax, 160 grs.; water to 20 ozs. (b) Soda carbonate, 4 ozs.; water to 20 ozs. Use equal parts of each. Solution (a) contains the minimum amount of sulphite necessary to prevent stain and give black images. We have lately reduced it to this minimum to avoid the restraining effect, which is fairly powerful. Previously we used one-fifth more of the two first ingredients in (a) and one-third the quantity of carbonate, and with this formula had the following curious and very unexpected experience. We were experimenting with a two-grain developer, i.e., we used one part of (a) with one part of (b) and two parts of water. This gave a weak image in five minutes, and we were trying the effect of varying the proportions. One part (a) with two of (b) and one of water was tried, and this gave a very slight increase of density. Two parts (a) with one of (b) and one of water was then used, but it gave no sign of an image in ten minutes. Thinking some mistake had occurred, we tried again with the same result. Fixation showed two faint and almost imperceptible ghosts of images, so in both cases the developer acted, though the excess of sulphite (even when combined with an excess of pyro) restrained it too powerfully. This is ample proof of the restraining power of sulphite. It is most convenient to keep a stock of the neutralised sulphite solution on hand, dissolving, say, 4 ozs. of sulphite and 1 oz. of metabisulphite in 40 ozs. of water. With 10 ozs. of this solution the pyro solution (a) can be made up at short notice. Twelve ounces of the sulphite stock gives the stronger (a) solution mentioned above. The one we have recommended has the advantage that it is more rapid in its action. It can be made up in double strength, but we are inclined to think that weak solutions keep best, and therefore do not recommend concentration.

\* \* \*

#### The Swung Lens in Press Photography.

The letter from a Tokio correspondent which we publish on another page raises a much debated point in hand camera construction. Mr. Ponting records his satisfaction with a swing movement of the lens of his reflex camera, in fact, he asserts that a large proportion of his success in dealing with scenes in the Orient is solely due to his ability to tilt the lens downward upon his subject. The reason of this will, of course, be clear to anyone who will draw a diagram of the path of the rays of light from the lens to the plate. He will see that the foreground immediately below the camera comes to a sharp focus at the upper part of the plate while, at the same time, the distance is sharply rendered on the middle and lower portion of the plate. In other words, the case—which we can well believe is a very frequent one in press photography—is one which makes a virtue of the movement. In general, opticians will demur to the camera maker providing a movement which permits the photographer wilfully to disturb the lens from its position of "squareness" with the plate, that is to say, the lens should be at right angles to the plate and not tilted at an angle. But that is, after all, a purely academic objection and presupposes that the subject before the camera lies all in one plane, that is to say, at equal distances from the camera lens. An ounce of Mr. Ponting's practice—that

of an expert worker—is worth a ton of theory, and it may be hoped that the swing movement which is not usually provided on high-class cameras intended for illustrative photography may be added. Possibly the spherical lens mount of Mr. Goole which we noticed a week or two ago will solve the difficulty, or it may be that Mr. A. L. Adams, who recently applied for patent protection for a “swinging lens,” has something of the kind up his sleeve which we shall see later embodied in one or other of his well known cameras.

### LENSES FOR STUDIO WORK.

“THE best lens for studio work” is a matter on which our advice is often asked in the “Answers” column. In the inquiries it is often mentioned that the studio is a very short one. These queries, as may be surmised, usually come from novices who are about to enter into the profession and know little or nothing about the optics of photography. Presumably their knowledge of professional portraiture is equally slight, or they would not erect the short studios that many have done. Some beginners seem to be under the impression that if they have a building with plenty of light in it, no matter how short it may be, that it will do for a photographic studio. Even last week we replied to a correspondent who proposes to build a studio that is only twelve feet long. What sort of perspective he expects to get in his pictures it is a little difficult to conjecture. It is for such as these the present article is penned.

If the whole profession throughout the kingdom were canvassed as to the lenses used for studio work it would be found that portrait lenses of the Petzval type—which were introduced more than sixty years ago—were more largely employed than all the other forms of lenses put together. This, we believe, is the present condition of things, notwithstanding the vast improvements that have been made in optical glasses during the past decade, improvements which have placed in the optician's hands the means of constructing instruments that seemed an impossibility twenty years ago. In face of these advances some surprise may be felt that the old Petzval lens is still so largely employed. The chief reason is its rapidity over all other forms—no mean consideration in portraiture. Petzval lenses having an aperture of nearly  $f/2$  are made by leading opticians. They were first introduced in the wet collodion days to meet the requirements of photographers in taking portraits of restless children, and for use in dull weather. They are, with this aperture, as a matter of course, somewhat costly. The price of the largest made in this country, which is from eight to nine inches focus, and for pictures of the carte size, is something like five-and-twenty pounds. With the present rapid dry plates there is little necessity for these exceptionally quick instruments. We see, however, from its recently issued catalogue, that an American house is making a specialty of these lenses up to fourteen-and-half inches focus, the price for this size being 500 dollars, equal to £100 English.

The most popular lenses at the present time for cabinet and carte portraits is what are styled by the various makers as “extra rapid portrait,” or “B.” lenses. They have an approximate aperture of  $f/3$ . The one most generally employed for the former size is from eleven to twelve inches focus and requires about eighteen or nineteen feet between camera and sitter. A lens of shorter focus than this is made for cabinet pictures, which requires only about twelve or thirteen feet between camera and sitter, but the makers, in their catalogues, do not recommend it if the length of the studio will admit of

the longer focus one being employed, as, with that, perspective is obtained in the pictures, by reason of greater distance from the sitter. The next most general lens in the studio is what is usually called the ordinary “portrait lens,” which has an aperture of  $f/4$ . It comes the “group or universal series,” sometimes “D.” lenses, which possess an aperture of  $f/6$ . These lenses are all of the Petzval type. Lenses of the rectilinear (R.R.) type are sometimes used in the studio, though, of course, they are very slow as compared with those of the foregoing, as their aperture is but  $f/8$ .

With regard to the relative rapidities of the above lenses, avoid going into decimals round figures are quoted, and will be near enough for practical purposes—supposing the most rapid,  $f/2.2$ , requires one second for exposure, given light, the  $f/3$  will require two seconds, the  $f/4$  three seconds, the  $f/6$  eight seconds, and the R.R.,  $f/8$ , sixteen seconds. Thus the R.R. will necessitate sixteen times exposure of the most rapid of the Petzval lenses. This it will be seen that the R.R. is not well suited for studio purposes except in a very good light.

There is another point in connection with lenses for studio that requires consideration, namely, what is known as “depth of focus.” The larger the aperture of a lens in proportion to its focal length the less depth of focus it gives—no matter what its form may be. Therefore, to obtain this the aperture must be reduced, and that, it goes without saying, at once makes the instrument slower in action. For example, if the  $f/2.2$  be stopped down to  $f/3$  it practically be no more rapid in action than the  $f/2.2$  worked at its full opening, neither will it have any greater depth of focus. Again, the  $f/3$ , if stopped down to  $f/4$ , will be no quicker than the ordinary portrait lens of  $f/4$  aperture, while the depth of focus will be the same in both, and so on with the other lenses.

The Petzval type of lens is an excellent one for the purposes for which it is employed, by reason of its large aperture and the fine definition it yields over a large field. But it has many defects as compared with lenses of more modern invention, such as the anastigmats. In the first instance, the field is very round, and though it can be flattened this can only be done at the expense of sharpness. In the best lenses of this type the makers have minimised these defects by a compromise between the two, and have thus been able to give us, as nearly as they can, what is required in practical portraiture. There is another defect in the Petzval lens, namely, the lack of illumination; the light falls off very much towards the margin of the picture, and it is for that reason that the form of lens has but a small field in proportion to its length, as compared with the modern anastigmats. These have not as yet been made of the same rapidity as the old Petzval lens.

Anastigmats of about seven and a half inches focus will cover the half-plate with their full opening of  $f/4$ , a little less are now being made. These would well cover the cabinet size; then the distance required between camera and lens for full length would be somewhere about ten feet. But we do not care to recommend such short focus lenses for portraiture. It has been generally recognised that in order to obtain the most pleasing perspective in portraiture the focus of the lens should be at least double the largest dimension of the picture. Therefore, a lens of the above focus is only suited for carte pictures, although it will cover the half-plate size. We had intended to have said something on the subject of short-focus lenses for portraiture, but want of space will not permit in this article. I shall probably deal with the question on some future occasion.

# FILTER YELLOW K.

The introduction of a new yellow dye by Meister, Lucius, and ... is an event worthy of notice. The yellow dyes at present in existence are mostly unsatisfactory, either in

The curves shown in Fig. 1 correspond to solutions of strength 1:4,000 and 1:16,000 c.m. It is easily seen from these that the absorption is gradual, and suitable for orthochromatic

ABSORPTION CURVE.

Fig. 1.

permanence or insolubility, the best being Flavazine T., or tartrazine, which, however, when used in dilute solution, permits the extreme ultra-violet to pass. There are two dyes at present which are greatly needed, the one a dye with absorption similar to tartrazine, i.e., gradual absorption, but which cuts out the whole of the ultra-violet; the other a dye with exceedingly sharp absorption, so that in very dilute solution it will cut out the ultra-violet without appreciably affecting the visible violet—dye with an absorption like potassium bichromate solution, for example. Filter yellow K. perfectly corresponds to the first of these dyes.

Fig. 2.

Fig. 3.

screens. Fig. 2 shows the spectrum of the enclosed arc photographed

(a) without a filter;  
(b) through filter yellow K. 1:4,000;  
(c) through filter yellow K. 1:16,000;  
(d) through tartrazine of such a strength that visually it is identical with (b). Fig. 3 shows the absorption of 1:4,000 filter yellow K. with differing exposures. The dye is very easily soluble in water, and mixes well with gelatine. As regards permanence, tests on this point have proved satisfactory.

C. E. KENNETH MEES.

S. H. WRATTEN.

R.P.S. LECTURES.—Sir William Abney has exchanged the date of his lecture with Mr. F. J. Mortimer. Sir William's lecture will now be given on Thursday, October 25, and Mr. Mortimer's on Thursday, October 18.

OZOBROME.—The Ozotype Company advise us that they are now fully booked for engagements for demonstrations of Ozobrome, and that it is impossible for Mr. Manley to undertake any more this season.

## THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

IN THE BRITISH JOURNAL OF PHOTOGRAPHY recently, there appeared a note on the subject of keeping a combined solution of sodium carbonate and sulphite. My experience, and the conclusions based on that experience, have been very different from those of the writer of the note in question. And, as it is of the greatest importance that there should be no misunderstanding in regard to the stability of developing solutions, my conclusions and the reasons for those conclusions are here given for consideration.

In the note referred to, many plate makers were criticised for giving in their developing formulæ a solution containing both sodium sulphite and sodium carbonate. The practice of keeping these two salts in solution together was condemned, the reason given being that such a solution was not stable, that the sulphite gradually changed into sulphate and retarded development and produced stained negatives. It was stated that such a solution would produce stainless negatives when freshly mixed, but if kept dirty and stained negatives would result.

For those who are continually developing a large number of plates the question possesses but little interest, they do not require to keep their solutions for any length of time; but for those whose work is intermittent or comparatively small in quantity, it is of the greatest importance that they should be in a position to assure the stability of solutions that may be required at any moment.

It has been my practice for a long time to keep a combined solution of sodium carbonate and sodium sulphite for developing, and many experiments have been made in regard to various methods of mixing the solutions, their stability and their efficacy for developing. My work is not extensive, solutions are frequently left for weeks without being required, but it is important that a solution should not only be ready for use whenever required, but also that there should be no variation in the quality, character or colour of the negatives produced. This has prompted me from time to time to test the relative merits of various methods of mixing both pyro and alkaline solutions; their developing qualities when freshly mixed and their power of retaining those qualities unimpaired.

The pyro solution consists of half an ounce of potassium metabisulphite, a quarter of an ounce of potassium bromide, and one ounce of pyro dissolved in sufficient water to make nine ounces and one drachm. Ten minims contain one grain of pyro. This method of keeping pyro in solution is the most simple and the most satisfactory that has been introduced. If properly mixed and stored its keeping properties appear to be unlimited; the working qualities will always be the same as if freshly prepared. In order to determine this point a severe test was made. A two-ounce bottle was partly filled with pyro solution and several small quantities were taken for developing from time to time. When the quantity was reduced to about five or six drachms the bottle was put away and left for nearly two years. The solution was then used for developing one of two duplicate plates, the other being developed with a solution that had only been mixed about an hour. The same alkaline solution was used for each plate. The development was carefully timed so that the treatment should be identical, and after fixing the two plates were exactly similar in gradation, density, colour and general quality.

Pyro will retain its qualities unimpaired in an acid sulphite solution, but not in any other form. Acid alone is useless, and a neutral or alkaline sulphite equally so. Potassium metabisulphite contains a large proportion of sulphurous acid, and

this acid sulphite forms a better preservative than any sulphite to which an acid has to be added. To obtain the greatest stability of the pyro solution it is imperative that the sulphite be thoroughly dissolved in the water before the pyro is added. The water may be made warm to facilitate the solution of the metabisulphite, though this should scarcely be necessary but it is very important that it should be quite cool before the pyro is added. When the pyro is dissolved the solution should be filtered, and it will then be very clear and a pale yellow colour. However long a time it may be kept it should retain this clear limpid character, and also remain the same colour.

The alkaline solution used in conjunction with the pyro solution previously given has consisted of equal quantities of sodium sulphite and sodium carbonate dissolved in water to make a twenty per cent. solution. The actual strength is simply a matter of convenience and facility in mixing the working solution for developing. With this alkaline solution there is no deterioration in quality or colour in the negatives, however long it may be kept. Nor is there any restraining or retarding effect visible as there would be if any appreciable proportion of sodium sulphate were present. In addition to its retarding effect sulphate is certainly a staining element. But in using this alkaline solution there has never been any staining tendency apparent, a change has very frequently been made from an old to a fresh solution when developing a series of exposures with no difference being visible in the negatives.

It is, however, very important that a reasonable degree of purity should be secured in the chemicals used. Several plate makers in the formulæ given for developing their plates specify "washing soda" for making the alkaline solution. The use of this form of sodium carbonate leads inevitably to staining, of inferior quality in the resultant negatives. Washing soda, though nominally sodium carbonate, contains a very large proportion of impurity, principally sodium sulphate, and should consequently never be used for developing solutions. Although the result produced by such a salt might be predicted with certainty by reason of its known character and impurities, the verification of the predicted result by means of an experimental test is always more satisfactory.

From a quantity of washing soda some clean, clear and good crystals were selected, free from powdery deposit on the surface or any apparent defect. With these a solution was made, of equal weight of good sulphite being added. The same proportion of this carbonate was added to the normal pyro solution, and would be taken of the ordinary carbonate for developing a correctly exposed plate. The resulting negatives were inferior in every respect. Development was more prolonged, and the plates were dirty and badly stained.

In describing the plates as being stained, it is necessary to discriminate between a negative that is brown in consequence of the composition of the developer not being favourable to the production of a pure black tone, and one that is really stained. In the former case, though the image may be very brown, the colour the shadows or clear portions may be fairly clear; in the case of a plate that is stained by reason of a decomposed developer, as in the case under consideration, it is the gelatin film that is stained. The image may be brown, but the clear portions of the plate will be a strong yellow.

Although this stained and defective quality has always resulted from the employment of such an inferior compound as washing soda, it has never resulted from the use of a combined

tion of good crystal sodium carbonate and sodium sulphite. The retention of the good qualities of such a solution would indicate that the deterioration only results when sulphate or other impurities are present when a solution is used.

Although a solution of sodium sulphite alone will not retain quality, yet other work than development has demonstrated that in the combined sulphite and carbonate solution the qualities of both sulphite and carbonate are fully retained. The negatives were bleached in mercuric bromide for intensification. After the usual washing one was treated with a freshly prepared solution of sodium sulphite; one with a similar solution had been mixed three or four days; and one with a combined solution of sodium carbonate and sodium sulphite had been mixed at least ten days. This was the usual developing solution containing equal quantities of the two salts. The three solutions applied to the bleached plates were approximately equal in strength of sulphite. The plates treated with the combined sulphite and carbonate and with the freshly mixed sulphite solutions respectively were identical in colour gradation and general quality after blackening. The operation proceeded normally, and no difference was perceptible at any stage.

The plate treated with the sulphite solution that had been mixed a few days previously would not blacken in the sulphate solution, and though the strength was increased by adding more from the stock solution the result was the same. The sulphite was quite inert so far as blackening the bleached plate was concerned; it had entirely lost its power. The action of the combined solution formed a marked contrast. It was apparent that however little stability a plain solution of sodium sulphite might possess the combined solution would retain the qualities of the sulphite quite as fully as those of the carbonate. And a long experience with the pyro and soda developer has confirmed the opinion that this applies equally to the developing qualities of the mixed solution.

A solution of pyro appears to be very stable if combined with an acid sulphite, and a solution of sodium carbonate in combination with sodium sulphite equally so. These two used together for developing produce negatives of good technical quality and free from stain. It is, however, an essential qualification that materials of good quality be used, otherwise the solutions contain the elements of instability when mixed, and can only produce negatives that are stained and defective.

HENRY W. BENNETT, F.R.P.S.

## THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

It is by no means an easy matter to review the show of the Royal Society: the critic's feelings are kept too placid there. An atmosphere of good behaviour, and even punctiliousness, pervades the place, leaving no loop-hole for the righteous indignation, the pettiness, and the satirical scorn which the purple patches of the Salon usually excite. These emotions add picturesqueness to a picture. One prop of the Linked Ring has quite recently admitted that perhaps there has been too much of the kind of thing that gives rise to these emotions; but if that gentleman has thoughts of leaving his house in order he should be disadvised; firstly, because there is not room for two exemplary photographic exhibitions in London, and secondly, because the administrative policy of the Linked Ring is to be proved the right one by the same gentleman's testimony to the present keen bay tree condition of the Salon, artistically and financially viewed. Therefore are we in favour of leaving things alone to develop along their respective lines. That "Royal" is developing is very apparent this year. Pictorial photography has never before been pushed so far towards that ideal, attainable or not, at which point it will establish unshakeable claims to be ranked among the fine arts. In pure decorative art, however, the Salon has, so far, gone furthest.

### Some Striking Portraits.

Reference has already been made to the portrait of "Alvin Coburn, Esq. (at the R.P.S.)." Mr. F. J. Mortimer is the author of this highly characteristic work. It is extremely difficult to get away from Mr. Coburn—if one wants to—in the two galleries this year. He appears twice at both as subject matter; and though, being a good "link," he does not exhibit here, he takes good that negation at the other place. Mr. Mortimer has taken him off delightfully. He stands invested with an air that is at once "sufficiently quaint and amusing." Boots and hat are blazing black, his trousers have a knife-edge crease, there is even a crease in the cut of his coat; Nash or Brummel could not have done with more of the *bon ton* upon a cane. There is but one anachronism about him, and that is his collar, which, alas! is a Victorian. The perfect pink of a gentlemanly showman, he stands before his own pictures, fearlessly proud to be identified with them. He is all in all at the Salon, and he is alpha and omega at the Royal, where his numbers are the first and the last in the pictorial row. Mr. E. O. Hoppé sends the last, certainly a good thing, and of a similar aspect; but it is too premeditated to possess the "go" of Mr. Mortimer's snapshot, and that premeditation has resulted

in the lugubrious look upon the sitter's face that has already been pointed out.

Several excellent portraits come from Mr. Furley Lewis, the best of which is, perhaps, that of "Hubert Carter." The unrestfulness of "Alessandro Moretti" spoils our pleasure in a fine work. The sitter, presumably a sculptor, holds a modelling-tool like a weapon in his clenched hand and has the alert watchfulness of a Nihilist. He seems to be crouching for a spring. The small bust in his hand might be for identification of his victim. Hence, we do not think it a happy portrait. Mr. W. D. Brodham's "Politician" is a work of much distinction; and the "Portrait of an Artist," by Mr. S. Holden (New York), is likewise worthy of note. We regret to find Mr. Dudley Hoyt (New York), who made a stir in past years, now represented by one work only, and that a "Portrait," a little lacking in the strong and masculine qualities he once displayed. It is very taking, nevertheless, and represents a lady dressed in a way that reminds us of Sophia and the Tom Jones circle.

Sig. Sciutto's portrait of a lady and gentleman standing ought to be mentioned for its strong and personal treatment: they look a most notable pair. But for personality, the head of Professor Brander Matthews will prove arresting, especially to those interested in spelling reform. This is by Mr. Pirie Macdonald (New York), who also sends "Louis Windmuller" a first-rate character study of an elderly smiling gentleman. "Louis Grier, Esq.," is by Mr. Walter Thomas, who is to be congratulated upon it. Two very distinguished *ritratti* come in the name of Sig. Ornano, from Genoa. The finest is something more than a portrait, however, for it depicts a young lady seated on a couch and leaning her head against its cushions with a sad introspective air that would be worthy of a more ambitious title. The delicacy and refinement of this beautiful little study will appeal to everybody.

The same worker sends "La Catena di Tristezza," a procession of three dolorous mediæval maidens. It is a flat and gloomy picture; but perhaps the title holds reason for that fact. A deeper and more mysterious picture forms an illustration to one of the plays of M. Maeterlinck. The atmosphere of tragedy surrounding the details of this is so thick that only the initiated can pick anything out of it. The somewhat ambitious "Suppliant" of Mr. S. Elwin Neame would make a more successful appeal were it not for its title. There is little that is supplicatory in the convolutions of limb and drapery of this handsome figure. It has a sense of style, and promises well for Mr. Neame. Leighton and Dorothy Deane seem to have been his inspiration. Two genre subjects by Mr. Hoppé,

to whom, by the way, both exhibitions are not a little indebted, merit attention because of their unsophisticated intent to be artistic without being unphotographic. These are "Visitors" and "Critic." The right-hand visitor is not free enough from self-consciousness to make a good model—a fault that practice cures; and the critic similarly seems herself apprehensive of criticism. Mr. T. Lee Syms does well in his two subjects, and particularly well in "Who Is It?" a lady upon a staircase, where a light effect has been handled in a masterly way.

### The Forbidden Duplicates.

With dashing temerity, Mr. E. T. Holding, and perhaps half a dozen others, have flouted the ukase of the Linked Ring by sending here duplicates of their Salon prints. We must conclude that after all then there was not "ample time" between the opening of each exhibition to prevent this previous disobedience. We ourselves think it desirable that these replicas should have some variation. A modification in treatment, for instance, would be educational: say a gum print at one place and a platinum at the other. At present, the only variation in duplicate exhibits seems to be in the spelling of the sender's name in the catalogue. Even that breaks the monotony.

### Babes and Sucklings.

Mr. Holding continues to do finer and finer work. We have already spoken in praise of his "Childhood." The demure and slightly vexed little "Kathleen" is a most taking study of young life, wherein the management of the child's hands is particularly praiseworthy. So is the fact that a very happy chance grouping of the girls who walk "On the Dunes" and who "compose" into such an agreeable shape, has not escaped the photographer's attention. It is in such little evidences of quiet artistic alertness that Mr. Holding's work promises so much for the future. His very reticence of manner implies wealth of matter. In "The Nation's Pictures" the posing of the youngsters and their own commendable control of their expressions make up the chief merit of the work. But is it not almost time that children had a rest from playing upon the floor in front of a camera? They have been at it some years now. Mr. L. Fleckenstein's little girl, a head and bust "Portrait," is a wondrous piece of lighting, and eloquent of the same infantile traits as is Mr. Holding's "Kathleen." As to "The Pet Angora," whilst we admit the charm of the turn of the cat's head, and its interrogative and apprehensive expression, we think it too furry in texture, and do not see that the lady who nurses the animal need have been made furry at all by Mr. Fleckenstein. M. Pierre Dubreuil occupies himself entirely with children this year. His "Petite Hollandaise" and "Four o'clock" are both nice works, the latter having an excellent light effect not free from traces of the "clumsy hand of man." Standing at a bath-room door is a little maiden with a wonderful outward curving line of leg, playing with "Le Bilboquet," and a sleeping babe upon its mother's knee is treated with exceptional daintiness in "Mother and Child." Mrs. C. Keene (Cape Town) has a similar subject nicely treated also. From Miss Towgood come two delightful little pieces. One is sweet and sunny, showing a young mother, or elder sister, seated at a window with a child who writes "The Letter" on a low stool. The other, "La Laveuse," is a capital study of an old woman, full of humorous character: she amuses a child as she washes. Admirers of Mr. Inston's work will be pleased with his "I don't want to play in your garden." They will find several other deserving child studies which we must leave unnoticed.

### Garrone and Duhrkoop.

We come now to the work of Sig. Garrone, which makes a finer show here than at the Salon. His delightful and sunny "In Domo Quies" is a peasant interior reminding one of Van Ostad. It is pleasing at a glance, and grows upon one; looks well at a distance, and repays scrutiny. "The Dente Canino" is one of the high window series of which we spoke when reviewing the Salon. This time a little boy, whose breeches are quaintly tucked into his boots, sits open-mouthed upon the lap of his mother, who makes a dental examination. In "Raggio di Sole" an older boy stands up in the window corner enjoying the rays of the sun. Sig. Garrone sets a good example to many. His fine, straightforward prints are neither murky nor washed-out; but at once rich and brilliant. In this

respect they resembled those of Herr Duhrkoop, who is well represented in this gallery. His now familiar sofa scene is here, under the doubtful name of "Twilight"—it seems to be broad daylight through the doors. The "Story Book" shows two girls reading. The little sorrowful in their bearing and expression; but the instinct with style. "In the Kitchen" and "In the Exhibition" will both win admirers; perhaps the latter particularly. It sends a lady examining a folio that rests upon a very "new" stool. The subject is of a kind favoured upon the Continent, wit, ladies in outdoor up-to-date dress with interior background. "After the Theatre," a lady at half-length, has a charming air regards us, in passing, with a sidelong inclination of the head.

### Figures Clothed.

Mrs. Barton has some good heads, as well as her early "St. Catherine," with which we have previously dealt. We wonder whether Miss K. Bingham ever saw the "Darker Drink" distinguished American a few years ago, or whether her work is an unconscious coincidence. "Watching and Waiting," by C. A. Morgan, is marked in our catalogue as a good thing. "The Gringo Came" exhibits the fact that a slight defect, such as a trifling cast in an eye, may add something like a further fascination to a face that is already beautiful. This charming head Miss Hana Robinson (California).

Miss Jeanne E. Bennett (Baltimore) (who is Mrs. a Salon), has a large number of pictures here; but we should be glad of fewer just a thought more distinguished. The all good, but only one can be called excellent, perhaps, and is "Listening to the Lark." Mr. Cavendish Morton is, as stylish and strong. Especially do these qualities belong to "Child," a work of fine arrangement and masterly treatment. His "Profile," a "Gibson Girl," is clever, too, in its way. We thought that the Dutch craze had burnt itself out; but Mr. Morton revives it in "Brothers" and "Brothers and Sisters." The being the more quaint and the less like a poster, we prefer it. The two girls with their little brothers all in a row are both good and pretty. Miss Hanscom's (California) pair of poetical stars are unequal in merit. "Go from Me" is by far the finer. The dark, but has quality and feeling. The other, "I Love Thee," misses fire, its pose being a little unhappy. Much nicer in respect is "The Ring," by Mr. J. Kauffman (Adelaide). This single figure in profile of a lady who contemplates a ring upon her finger. The beauty of the sitter, in pose and features, secures success of this. As a picture, it is without the charm of the autumn "Winter Mist," a landscape print of delightful greys, where the peasant woman is washing clothes.

### Figures Unclothed.

Messrs. E. B. Vignoles and P. S. Greig share between them honours of "Whither?" a very naked variety of the nude, giving the figure of a young man who seems uncomfortable and out of place upon some rocks. "A Study in Pose," by Mr. Berli Jackson, is a little too reminiscent of "strong" men. Male figure for some unknown reason, do not lend themselves to graceful play. "The Study," sent by Herr D. Feledi (Budapest) is pleasing in its lines, although the head is commonplace. On whole, the essays in the nude from Miss B. Johnson please us. They are very tastefully used as accessories to landscape. "Visions" is quite in the style of M. Le Begue, with its charming little figure contemplating its own reflection in a stream. "Springtime," on the other hand, has the Puyo feeling. Here the play of a musical nymph in a romantic sylvan glade is artistically managed, and is quite in accordance with valued traditions. A nude boy, by Miss Bennett, does not rise beyond "The Study" merely claims to be.

### Landscape.

A happy selection with very pleasant colour and quality made out Mr. R. S. Kaufman's "Waterway" as a thing not to be missed. Near to this may be seen a misty picture by Mr. Underhill, where a sea-serpent seems to lay its sinuous tail over a quay side. A more pleasing selection is Mr. Oscar Hardee's "Bruges Canal," a covetable print, less hackneyed than his "Ostend Harbour." Mr. L. J. Steele sends two noteworthy Oriental subjects, the finer being "The Garden of Allah." This impressive work depicts a lone

camel-ride upon a desert over which the last rays of sunset stream. Another pair of good things come from Mr. W. J. Clutterbuck, and the most distinguished of these is "Grandpère," in reality a glittering landscape. We like very much Mr. Hector Maclean's "Reticence of Nightfall," and we could say the same of the well-considered works of Mr. J. Gale, if it were not that he spoils his good compositions by sousing them in a brown sauce which robs them of light. In this matter his "Upper Pool, London," is least open to objection. The stately compositions of Mr. J. H. Gear and Mr. Greatbatch lose charm for us from the same cause.

Were it not that "Twilight's Contemplative Hour," by Mr. H. Stuart, is somewhat sharp in its contrasts, it would take its place in the highest rank of homely landscape shown in these galleries. Four pictures, by another Mr. Stuart (Charles F.), are attracting considerable attention; deservedly so, as we think. Those that please us best are "Summer's Noontide," a river and trees well composed, and "Evening," a fine open view with lengthening shadows and a capital effect of light in the sky. The light in the sky and water of Mr. Harold Moore's "Gravesend Reach" is likewise the cause of great success. In his "Winter Oats" he gives us no sky at all, a distinct disadvantage to a subject that everyone must associate with skies and open air. A similar indiscretion has been committed by Mr. Porterfield (Buffalo), whose "Sunrise on a Misty Morn" is printed in blue, a choice which cuts off all pictorial help from mental associations. It is otherwise unexceptionable.

Mr. Mummery's two works will uphold his reputation well. The general favourite seems to be "Evening in Winter," a solemn and sweet river scene with fine trees and a good effect; but we are not sure whether there are not more artistic qualities still in the more free feeling of "The Dike Gate." A very delightful view of "Old Shoreham," backed by a splendid sky, ought to do much for the reputation of Mr. Colebrook. The print is beautifully mounted too. His "Water Meadows" is only a trifle less interesting. Mr. W. Rawlings's work, good as it is, does not seem to surpass previous efforts of his. We are most taken with "The Wayside Inn"—our weakness, perhaps—and its sun and thunder aspect. In the beautiful and dreamy "Venice" we feel that Mr. Alfred Marshall has permitted too much foreground, if water can make foreground. The horizon must have been low to his eyes, if the photographer was in a small boat. Perhaps the most romantic landscape in the show is the remarkable "Nebeltag," sent from Graz by Dr. Ledenig. It shows a pool glimmering through the naked stems of thin trees, the whole being softened and veiled in the vaporous beams of a sinking sun of a foggy day. Other romantic things come from Vienna, sent by Herr Pichler. We have already referred to "Der Wachter," which our printers preferred to call "Der Waihter" after the catalogue than follow our correction. In "Sonnenaufgang" we have an impressive ceremony in which many models have played their parts. Its only fault to us is the forcing of the light upon the

principal figure, for this has the taint of staginess. "Arkadien" is a stately landscape filled with tall trees which might be great aspens. Beneath the shade of these five boys (satyrs?) dance in a ring. The whole thing is much in the style of the best modern German painting. In fact, "San Vigilio" is Boecklin's stupendous "Totteninsel" over again. The title of "Sonnenfunken" is thoroughly well carried out in the sparkling sunbeams that patch and bejewel the walls and vines of an Italian garden, where some people are lounging. Mr. J. M. Whitehead has been fortunate this year. His "Nightfall on the Moor" is, perhaps, the best of his works. There are few things here more beautifully true to nature, and it is perfectly composed. Mr. S. E. Wall's "November" is full of feeling; but we fear he has let his roadway come a little too dark for a November evening. A subject of river and barges has been well managed in Mr. E. Warner's hands, and another shipping subject, "The Port—Dawn," is true to the effect claimed in its title, as observant early risers will bear out. We must commend the light and graceful "Pool at Oxshott," by Mr. William Stevenson, and "The Medway at Rochester," by Mr. Piddington. The latter is a capital subject, brightly treated in gum. "Mid Ocean" is, as its title implies, one of a new series by Mr. Mortimer. Hitherto his reputation has rested upon wave studies from the shore, but now he is amongst them, and gives well the broad, hazy, and somewhat monotonous light that envelopes all upon mid-ocean.

Why has Mr. Bushe-Fox scrawled the title of "Winter Sunshine" across his first-class print?

The same material is used both by Mr. H. Symes in "Ebbing Tide" and by Mr. C. J. Reade in "Reflections." The work is good in either case; but "Reflection" has the better selection. Snow, such as Eickemeyer has given us, and not less beautiful, appears in Mr. Sykes's "Winter." Mr. Batkin gets a good deal of broad style into his cart and street corner composition, which he calls (with a bent for novelty) "Sunshine and Shade."

#### Colour.

There are a few attempts at colour, but we are disposed to think that they are not greatly successful. In Dr. Ledenig's "Blühende Baume" the colour certainly only hardens lines already hard, and is entirely without beauty or gradation. Much the same applies to Herr Feledi's "Fischer's Arcade," where the colour has only a cheapening effect. In the "Danish Landscape," signed T. Möller, it is distinctly unpleasant. The pigment in these cases is arrived at by gum printing, which, like lithography, must be complex in method to be good. Against this we must say that where it is mechanically arrived at, as in the case of "Mr. Cavenish Morton's "Child of Egypt" and Mr. William Gill's "Strawberries," is undoubtedly more satisfying and more true, though perhaps not so "distinguished."

[The review of the professional section of the exhibition will appear next week.]

## THE PHOTOGRAPHIC SALON.

### CONCLUDING NOTICE.

#### Noteworthy Landscapes.

Two receding planes of Mr. J. P. Hodgins's cypress avenue almost make a picture of it; but to call it "Landscape" is to give it a misnomer. Mr. Archibald Cochrane's "Lane in Brittany" is, on the other hand, a landscape so highly pictorial as not quite to avoid the charge of conventionality. Its cloud—a leading feature—particularly betrays studio anxieties. Mr. Ward Muir's landscapes are more unsophisticated, but have less of the same pictorial feeling which, after all, is not a common gift. We do not care for his "Winter," for we refuse to receive white paper for snow. "The Pageant of the Sky," however, appeals to us as a fine example of photographic landscape proper, selected and carried through with evident appreciation of the beauties of Nature. Its fine cloud and the low horizon evidence the fact that Mr. Muir knows what he wants and gets it. Similar praise is due to Mr. J. M. Whitehead for his very romantic work "From the Cloudland." How different is the aimless and affected "Nuit Imminente, Etude Japonaise" of Mr. E. O. Hoppe! The same gentleman's "Adagio" would be a first-rate little character

study were the old musician of our grandfathers' time, playing more and posing less. Another highly pictorial landscape is "Wash," by Mr. W. J. Clutterbuck. It consists of sheep, shepherds, and trees beautifully composed and making a fine design according to the principles of early British artists, of which principles photographers remain too much in ignorance. Mr. Clutterbuck has also a marine subject of fine design, called "In the Trades," wherein a barge and its sail are disposed upon the most attractive lines. Of Mr. J. Dudley-Johnston's pictures we like "An Impression—The River Medlock," because, at any rate, it is impressive; and his "In Normandy," because it has the rare and undefinable quality of an etching.

#### Interportraiture.

Mr. Reginald Craigie takes the likeness of Mr. Coburn; Baron A. de Meyer does the same; Mr. Frederick Hollyer takes Mr. Horsley Hinton; Mrs. Käsebieber takes Mr. Alfred Stieglitz; and so they go on, a happy family, forging the indestructible links of a ring of friendship. As portraiture, all these works are distinctly good; but as

likenesses they are a little baffling. But the recipients of these pretty courtesies do not look their respective gift horses in the mouth. Yet, to an outsider, it is not easy to recognise Mr. Coburn without a head covering. Baron de Meyer must have appreciated this fact when he rightly elected to give us the coat, etc., which in this case makes the man. The early Victorian glamour that surrounds his subject has had one drawback, however, for the Baron. It has called up association with certain time-honoured civic functionaries whose livery has survived the date of its inception, and the result is that the Baron's Mr. Coburn looks like a turncock. Mr. Craigie's version has a touch of it, too, for it resembles those exemplary middle-aged artisans which in our youth used to point the morals and adorn the tales of "The British Workman." We positively did not know Mr. Horsley Hinton from Mr. Hollyer's presentment, and remarking on this fact to the sitter himself, we were answered that perhaps we were not in the habit of seeing him in frock coat and "top" hat. So it is evident that the dictum of Bob Acres about clothes continues to hold strongly in these days.

### A Designer of First Rank.

With delight, pure and unalloyed, we contemplate the very distinguished designs of Mr. F. Benedict Herzog. His "Barye-Sculpture" gives complete satisfaction in the arrangement of its lines and the display of its light and shade. Anything more purely decorative than this work (except his other) it is difficult to imagine in the domain of photography. The draperies of the figure leaning out to the statuette of a lion—one of the masterpieces of the French animal sculptor, Barye—are disposed with grace, and treated with loving respect to the traditions of decorative art. The same applies to his second work, "Alas, poor Yorick!" which is of higher ambition, and entailed greater risk and difficulty. The titles are not happily chosen in either case. There is nothing at all of Yorick, except his dry skull, in a composition of three ladies—Ophelia and two waiting women. The real title and explanation is found in the quotation, tastefully lettered beneath the print:—"Now get you to my lady's chamber, and tell her, let her paint an inch thick, to this favour she must come." What we see in the expressions of these three handsome women is the effect of this scrap of cruel philosophy upon their minds. The posing and acting of the three superlatively clever models who sat for this work reflects the highest possible praise upon them and the designer alike. Both these prints are small in size, but colossal in style and beauty. To the really artistic visitor they will be the real sensation, making him draw in the breath, whereas at the calculated sensation he will but snort it out.

### Architectural Triumphs.

In the field of architecture pictorially presented, this exhibition is remarkably strong. The finest group of all is, perhaps, Mr. Arthur Marshall's "Venetian Pearl," a view of the Maria della Salute bathed in the transfiguring vapours of a sunny mist. His "Precious Stones" is good, too, but not quite so pictorial. Mr. Frederick H. Evans delights us in his usual way by using sunshine

as an illuminant of dark, put precious, corners rather than as a to add mystery. Mr. Marshall's method is synthetical; Mr. Evans analytical. His pictures, with their unconventional points of view taken at Mont St. Michel, Chartres, and in homely Norfolk, things to live with and pore over. A hasty glance does not reveal their charms. In Mr. S. G. Kimber's "Relic of the Past" and "Cathedral Passage" we have keen sensations of the distance depth of architectural vistas and cavernous places. A view "Lombard Street," by Mr. Eustace Calland, is truly pictorial artistic. The best of Mr. Alex. Keighley's works is, in our opinion "The Bridge," a fine snapshot of peasant women walking over Italian town bridge, mischievous boys on the flagstones in the corn and sails peeping over the cornice. His "Calle del Duca Chioggia" is a good subject, with decorative and pictorial claim but it is rather monotonous in its tones. Germane to this sub is the splendid and humorous "Truants," by Mr. P. G. R. Wright wherein two urchins are being marched away by a peasant woman in the sunlit street of some Continental town.

Shipping and the overwhelming structures of steel and iron in port of Liverpool and New York make up Mr. A. L. Coburn's contribution. We think he might exercise a little more rigorous selection in his works for exhibition. It does not follow that because he has done many fine things that any and every snapshot out the thousands he has taken are good enough for enlargement and display. At any rate "The Prow" should have been eliminated. We see nothing at all to recommend it. The reflection of rigging "Spider Webs" makes an entertaining subject; but only to those who have not had years of that sort of thing in photographs. Like "The Rudder" the best, because it makes some claims for composition, and shows a pleasing filtration of light into the recesses of a world of ironwork. The whole of this group of pictures, however, is aggressive, with awkward, hard lines and staring black patches and we feel sure that in a year or two Mr. Coburn will turn from better work to these with something like guilty feelings. The waterside piece that M. P. Dubreuil sends, called "Le Cygne," is quaint and good; but there is much that is only silly in "Pierrot Sleeping." We like better Miss E. Spencer's "In the Garden," which has grace of line at least. Mr. E. T. Holden's "Childhood" is very pretty and deserving of notice.

Amongst the exhibitors who have been allowed a quite disproportionate amount of space is Herr Heinrich Kühn. We say so, not because his work is of insufficient excellence, but because it is all so similar in style that one or two examples would adequately represent it. We cannot mention any one particularly fine among his eight: they are all fine, though a little "precious" for preciosity sake; yet rich in tone, strong in conception, and sane in execution. Of Baron de Meyer's half-dozen we prefer the beautiful "M. Francis Koehler"; and of Mrs. Käsebieber's five, the "Josephine" decidedly, because of its charm and quality.

We ought not to conclude without a word of appreciation for the fine and true qualities of light in "Late Afternoon," a choice landscape, by Mr. Charles Job.

## ON THE STABILITY OF VARIOUS ANILINE DYES AND THEIR BEHAVIOUR AS PRINTING INKS.

A Paper in the "Chemiker Zeitung."

SUPPLEMENTING my previously published work on this subject (see Eder and Valenta Beiträge zur Photochemie und Spectralanalyse; (V. Teil, Vienna, 1904) I have, during the current year, examined a number of dyes made by the Farbwerke vorm Meister, Lucius and Bruning of Höchst, the Badische Anilin und Soda-Fabrik of Ludwigshafen, and L. Cassella and Co., of Frankfort, and intended for making colour lakes. Whilst in previous years the aniline dyes mostly used for making lake colours gave brilliant hues, which were by no means stable to light, the efforts of the large firms are now to prepare dyes suitable for making lakes which shall not only be brilliant, but also stable to light, and answer in other respects to the requirements of the lithographer, the collotype worker, and the half-tone printer. These products are met with commercially under various names as

lakes, which are not very stable to light, but which are dazzling in brilliancy.

It is in any case of great interest to the inkmaker, as well as the printer, to know what are the qualities of the various dyes as printing inks, and, above all, to know their behaviour under the action of light and air and their printing powers. As regards the stability of a printing ink to light, it is interesting to know how it behaves in various thicknesses, as there are many colours of excellent shade and printing power, which, printed in thick films, are very stable to light; whilst in thin films are completely altered or bleached with the same exposure. The result of using such colour in an ink is that by exposure to light the pictures present a totally different appearance, as the delicate half-tones and middle tints at

leached or otherwise altered, whilst the deep tints remain the same.

### Making the Printing Plates.

In the process previously used (loc. cit) by me for testing the covering power and stability of the printing inks, only deeply printed surfaces were exposed. In order, however, to test the finer parts of the process was altered, so that instead of one single deeply printed surface, four films of varying thickness were exposed. To make these colour films a copper plate was used, on which were four squares with 8cm. sides etched to various depths. These squares, when printed on a sheet of paper, gave four different thicknesses of colour of varying intensity. The ratio of the colours was measured by a colorimeter, and the ratios found were 100:80:50:10. The strongest film (I.) corresponds to the deep tones, the middle films (II. and III.) correspond to the middle tones, and the thinnest film (IV.) to the most delicate tints of a picture. This printing plate, when printed in a copper-plate printing press, gave a chart which enabled one to study the action of light on the colour of the inks by covering the half of each square with black paper. The dyes, which were so generously provided by the above-named firms, were prepared as colour lakes, mostly according to the formulae worked out by the said firm, and with the minimum of varnish rubbed up into inks. With these inks pulls were obtained on paper, free from wood pulp, and these were simultaneously exposed with the standard colour, alizarine red lake, to

the action of sunlight, half of each individual square being protected by black paper. After the lapse of forty-eight or fifty-six days the tests were removed from the printing frames, and the loss in colour estimated by a colorimeter, and compared with the standard colour, which was taken as = 1000. The colorimeter used was Wolf's, which was fitted with a Zummer-Brodhun prism, as in my previous experiments. I found this to be more accurate than the one fitted by the makers.

### The Method of Testing.

The method of testing was as follows:—Under the left tube of the colorimeter, filled with water, was placed the unexposed square of colour; under the right tube was placed a piece of white unprinted copper-plate paper. The right tube was then filled with a solution of a dye which exactly corresponded, as regards colour, with the printing ink to be tested, and then by running it out or the addition of concentrated dye solution, the two fields were matched as regards intensity and colour. Finally, if necessary, it was filled with water up to the 100 division; in place of the unexposed colour square the exposed square was placed under the left tube and the solution run out of the right tube till absolute equality in colour intensity was obtained. The number of divisions corresponding to the liquid run out gives the loss in colour, caused by the exposure, direct in percentages. The results obtained are given in the following table:—

### Red Dyes.

Dye.	Precipitation.	Ratio of Varnish Colour.	Loss of Colour.		Stability to Light—Alizarine Red Lake = 1,000		Remarks.
			Per Cent.		I.	IV.	
Alizarinrot..... Bluish in parts. B.A.S.F.	Maker's formula .....	2:3 2:3	1 2	IV. 12	1,000 1,000	1,000 1,000	The standard colour lake. The other dyes were exposed with this to sunlight, some for 48 and others 56 days.
1. Pigmentscharlach 3B ..... Azo dye. M.L. and B. Ger. Pat. 141,357—24.10.1902.	Baryta lake on alumina hydrate according to maker's formula	1:3	2.5	16	1,000	875	Brilliant pure red, prints well and evenly. Is very stable, the delicate half-tones withstand the action of sunlight well, and only become slightly bluer. Exposure, 56 days.
2. Pigmentscharlach G. .... Azo dye. M.L. and B.	Like No. 131 .....	2:3	7	65	357	215	Behaves like No. 131 as regards printing, but is less stable. The whites with both sorts are clean. Exposure, 56 days.
3. Echterorange O. .... Azo dye. M.L. and B. Ger. Pat. 129,538—7.8.1901.	Baryta lake on alumina hydrate .....	1:3	7	40	357	300	Brilliant orange red, prints well and bleaches evenly without change of tint. Good stability. The whites remain clean. Exposure, 56 days.
4. Permanentrot 6 B. .... Azo dye. A.G.F.A.	Baryta lake on alumina hydrate and barium sulphate	2:3	9	82	277	170	Bluish red, prints well, bleaches equally in light. Good stability in the deep and middle tones. The lake requires very careful rubbing up with the varnish. The whites are only slightly tinted. Exposure, 56 days.
5. Autolrot BGE ..... B.A.S.F.	Mixed direct with alumina hydrate paste 5 p.c., 1:3	2:3	12	Over 100	208	—	Yellowish red, prints brilliantly, but in thin films, the delicate half-tones, not very stable. Whites somewhat tinted. Exposure, 56 days.
6. Baumwollscharlach extra ..... Azo dye. B.A.S.F.	Dye 6, water 1,000, aluminium sulphate 100, chalk 52, with Turkish red oil 30; precipitation with barium chloride solution (100:500)	1:3	12	60	208	223	Very pure fiery red, prints well and suffers no important change of tint in light. Whites clean. Exposure, 56 days.
7. Permanentrot 4 B. .... Azo dye. A.G.F.A.	Baryta lake on barium sulphate and alumina hydrate, according to maker's formula	1:3	20	98	125	143	Yellowish red of great brilliancy, prints well, gives pure whites, and in bleaching the tint hardly alters. Exposure, 56 days.
8. Lackrot P. .... Azo dye. M.L. and B. Ger. Pat. 128,456.	Baryta lake on alumina hydrate, according to maker's formula	1:3	20	44	125	313	Fiery yellowish red, prints very well, bleaches evenly and slowly. The delicate half-tones are stable. The lake only alters slightly in tint. The whites keep clean. Exposure, 56 days.
9. Autolrot BL ..... Azo dye. B.A.S.F.	As No. 135 .....	1:3	20	Over 100	125	—	The fiery lake prints well, the whites keep clean, but the delicate half-tones are very fugitive. Exposure, 56 days.
10. Astazinrot B ..... Azo dye. B.A.S.F.	Baryta lake on alumina hydrate, according to maker's formula	2:3	30	80	83	175	Yellowish brilliant red, prints well. The whites keep clean. Can be varnished. Exposure, 56 days.
11. Pigmentrot G. .... Azo dye. M.L. and B.	Barium sulphate and alumina hydrate	1:3	30	Over 100	83	—	Yellowish red, the lake requires very division by long rubbing with the varnish if it is to print well. The whites keep clean. Exposure, 56 days.

## Red Dyes.—Continued.

No.	Dye.	Precipitation.	Ratio of Varnish Colour.	Loss of Colour. Per Cent.	Stability to Light-Alizarine Red Lake = 1,000.	Remarks.
142.	Pigmentrot B. Azo dye. M.L. and B.	As No. 141	1 : 3	I. 30 IV. Over 100	I. 83 IV. —	Bluish red. The lake behaves like N Exposure, 56 days.
143.	Brilliant Lackrot B. Paste. Azo dye. M.L. & B.	Dye 100, H <sub>2</sub> O <sub>900</sub> , Turkish red oil 10 (diluted with water to 100), 70 Ba Cl <sub>2</sub> 10 p.c. sol. After boiling 900 alumina hydrate (10 p.c.) added	2 : 3	48 Over 100	52 —	Yellowish red, prints well. The colour comes bluer in light, it is less stable than the delicate half-tones. The colour requires very fine rubbing with the varnish. Exposure, 56 days.
144.	Astazinrot G extra B.A.S.F.	Baryta lake on alumina hydrate...	1 : 1	52 84	48 168	Yellowish red, prints well. Whites clean. No important change of colour in bright light. The dye is not very satisfactory. Exposure, 56 days.
145.	Pigmentbordeaux N. Azo dye. M.L. and B.	On baryta according to maker's formula	1 : 3	66 Over 100	38 —	Violet red, prints very well. The colour changes in light, particularly in the deep tones, and becomes yellowish. Exposure, 56 days.
146.	Antolrot BLP. In paste 20 per cent. B.A.S.F.	As No. 137	1 : 1	67 Over 100	38 —	Bordeaux red colour lake, prints well. Rubbed up finely with varnish. The delicate half-tones bleach fairly quickly. Middle tones become yellowish. Exposure, 56 days.
147.	Eosinsäure L (new) B.A.S.F.	Lead lake. The dye was dissolved in soda solution, precipitated with H <sub>2</sub> SO <sub>4</sub> , the necessary quantity of sugar of lead solution added and boiled for 1 hour	2 : 3	70 Over 100	36 —	Extraordinarily brilliant bluish red, prints very well, gives pure whites, and is more stable than the ordinary rosine lakes. The deep tints the prints show more reflection. Exposure, 56 days.
148.	Permanentorange Azo dye. A.G.F.A.	Baryta lake as No. 134	1 : 3	70 Over 100	36 —	Brilliant good printing orange red. There is some loss of brilliancy in the deep tones in light, the delicate tints bleach fairly quickly. The whites are slightly tinted. Exposure, 56 days.
149.	Pigmentorange R. Azo dye. M.L. and B.	As for No. 145	1 : 3	75 92	27 130	Brilliant orange red, prints well and even if rubbed up very fine with the varnish. Whites clean. Exposure, 45 days.
150.	Azo dye from Nitro-aniline-sulphonic acid and $\beta$ -naphthol. B.A.S.F.	Baryta lake on alumina hydrate, according to maker's formula	1 : 2	78 Over 100	32 —	Orange red lake, prints well. Whites clean. The colour alters in light, especially the half tones and becomes yellowish. Exposure, 56 days.
151.	Litholrot G G. B.A.S.F.	The dye paste was mixed with nine times the quantity of alumina hydrate (4 p.c.)	2 : 3	84 Over 100	29 —	Bright yellowish red, prints well. The colour in the deep tones becomes yellowish in light. The delicate tints bleach fairly quickly. Exposure, 56 days.
152.	Litholrot G G. B.A.S.F.	As with 151, only there was also 20 p.c. of the weight of the paste of BaCl <sub>2</sub> added	2 : 3	84 Over 100	29 —	Behaviour as No. 151. Whites clean. Exposure, 56 days.
153.	Litholrot R. B.A.S.F.	As No. 152	2 : 3	90 Over 100	27 —	Bright bluish red, prints well. The colour becomes yellower in light. The whites were fairly clean. Exposure, 56 days.
154.	Brilliantcarmin L. B.A.S.F.	Baryta lake on barium sulphate.	2 : 3	92 Over 100	27 —	Fiery red, prints well. The colour alters in light and becomes yellower. The whites are fairly tinted. Exposure, 56 days.
155.	Lackrot C. Azo dye in paste. M.L. and B.	Baryta lake on alumina hydrate.	1 : 1	93 Over 100	27 —	Fiery yellowish red, prints well, is however very fugitive as regards the middle and delicate half-tones. Whites fairly tinted. Exposure, 56 days.
156.	Litholrot R. B.A.S.F.	As No. 153, but instead of BaCl <sub>2</sub> sugar of lead solution was added	2 : 3	94 Over 100	26 —	Very fiery red, bluish, the colour does not change in light, but the middle and lighter tones bleach. Exposure, 56 days.
157.	Litholrot R. B.A.S.F.	As No. 153 but CaCl <sub>2</sub> used instead of BaCl <sub>2</sub>	2 : 3	95 Over 100	26 —	Behaves like 156, but the colour alters in light and becomes yellower. Whites pure. Exposure, 56 days.
158.	Pigmentpurpur A. Azo dye. M.L. and B.	As No. 149	1 : 3	95 Over 100	26 —	Brilliant deep bluish red, prints well, is very fugitive. The half-tones bleach completely. Whites slightly tinted. Exposure, 56 days.
159.	Litholrot R. B.A.S.F.	Dye mixed with ten times the quantity alumina hydrate paste (4 p.c.)	1 : 3	96 Over 100	26 —	Fiery bluish red, prints well, is however very fugitive. The middle and delicate half-tones bleach quickly. The deep tones keep better, the colour alters slightly bleaching. Exposure, 56 days.
Yellow Dyes.						
160.	Alizarinengelb 5 G. B.A.S.F.	As alumina lake and then boiled with addition of Turkish red oil	1 : 3	2 50	1,000 240	Rather brownish yellow. The middle tones III. and IV. are purer; the colour becomes browner in light. Prints well. Whites clean. Exposure, 48 days.
161.	Pigmentechtgelb G. Azo dye. M.L. and B.	Baryta lake on alumina hydrate	1 : 3	2 49	1,000 245	Brilliant yellow, the brightest tones almost citron yellow, middle pure golden yellow. Prints very well. The colour does not change in light. Probably suitable for three colour work. Exposure, 48 days.

## Yellow Dyes.—Continued.

No.	Dye.	Precipitation.	Ratio of Varnish Colour.	Loss of Colour.		Stability to Light—Alizarine Red Lake = 1,000.		Remarks.
				I.	IV.	I.	IV.	
162.	Pigmentechtgelb R. Azo dye. M.L. and B.	As No. 149	2 : 3	18	45	125	230	Rather dull yellow. Prints well. The colour changes slightly in light, becoming browner. Whites pure. Exposure, 48 days.
163.	Pigmentchromgelb L. Azo dye. M.L. and B.	As No. 149	2 : 3	18	66	111	182	Somewhat brownish yellow. In light the colour does not alter. Prints well. Whites pure. Exposure, 48 days.
164.	Pigmentchlorin G G. M.L. and B.	As No. 149	1 : 3	20	50	100	240	Brilliant, slightly greenish yellow. Turns browner in light. Prints well. Whites clean. Exposure, 48 days.
165.	Flavazin 3 GL. M.L. and B.	Baryta lake on alumina hydrate	1 : 3	35	60	57	200	Golden yellow, prints well. Whites clean. The colour only alters slightly in light. Exposure, 48 days.
166.	Flavazin 3 GL. M.L. and B.	Alumina tin lake on alumina hydrate	1 : 3	52	75	38	160	Brownish yellow. Exposure, 48 days.

## Blue and Violet Dyes.

167.	Indanthren S. B.A.S.F.	Dye rubbed up direct with alumina paste	2 : 3	0	0	Over 2,000	Over 12,000	Tegethoff blue, prints very well, and does not alter in light. The printing ink is of extraordinary great stability to light. Exposure, 48 days.
168.	Alkaliblau For printing ink. B.A.S.F.	Rubbed up direct with the varnish	2 : 3	7	51	286	148	The blue dye is intended as an addition to black inks to make them bluer. Rubbed up by itself with varnish it gives tinted whites. Exposure, 48 days.
169.	Oxaminblau G N. B.A.S.F.	Rubbed up with alumina hydrate paste and Cu SO <sub>4</sub> added	2 : 3	7	57	286	210	Greyish blue colour, prints well, alters slightly in light (darker in the deep tones). Exposure, 48 days.
170.	Lanacylviolet 3 B. Cassella.	Baryta lake on alumina hydrate and baryta according to maker's formula	1 : 3	14	46	143	260	Fiery violet, prints well, becomes slightly redder in light. Exposure, 48 days.
171.	Oxaminpferblau R R. Azo dye. B.A.S.F.	As No. 169	2 : 3	16	43	125	300	Blue violet colour, becomes redder in the light. Exposure, 48 days.
172.	Immediatreinblau conc. Sulfin dye Cassella	Baryta lake on alumina hydrate and baryta According to maker's formula	1 : 3	50	64	40	183	Beautiful fiery blue (ultramarine), prints well. The colour changes in light and becomes grey blue. Exposure, 48 days.
173.	Viktoriblau G N. B.A.S.F.	With Tamarin and tartar emetic on alumina hydrate	1 : 3	86	Over 100	23	—	Pure very fiery blue, prints well, is fugitive, and the colour alters. Exposure, 48 days.
174.	Säureviolet P W. B.A.S.F.	Baryta lake on barium sulphate	1 : 30	90	Over 100	22	—	Fiery blue (Kaiser blue), rather fugitive, bleaches quickly with change of colour. Exposure, 48 days.

## Green Dyes.

175.	Lichtgrün S L. B.A.S.F.	Baryta lake on barium sulphate	1 : 3	92	Over 100	22	—	Fiery green, the colour alters quickly in light, and is especially fugitive in the half-tones. Exposure, 48 days.
176.	Lackgrün B W. B.A.S.F.	Baryta lake on alumina hydrate	1 : 3	95	Over 100	21	—	Brilliant blueish green, but the colour changes quickly, and completely bleaches in the half-tones. Exposure, 48 days.

As regards the preparation of the colour lakes in the above table, it should be noted that most of the dyes were precipitated as baryta and alumina lakes, some with lime or tin salt. Dyes, such as pigmentchlorin GG, pigmentchromgelb, pigmentorange, pigmentrot, and pigmentbordeaux, which do not contain any salt-forming group, were mixed, like litholrot, with water and the medium, with or without the addition of salts Ba Cl<sub>2</sub> Ca Cl<sub>2</sub>, etc.). Viktoriblau was precipitated with tannin and tartar emetic in the usual way.

As will be seen from the above table, there is a fairly large percentage amongst the dyes tested, which are sufficiently stable to light to satisfy the requirements of a good printing ink. Individual dyes even give strikingly stable colour lakes, such as pigmentschlarlach 3B of the firm Farbwerke Meister, Lucius, and Bruning. This dye, which is prepared by diazotising o-amidobenzoic acid and coupled with  $\beta$ -naphthol-3-6-disulphonic acid only gives pure red lakes of considerable stability to light in the deep as well as the delicate tints if the carboxyl group takes part in the lake formation, whilst with subsequent treatment of the dye solution mixed with alumina paste or aluminium sulphate with barium chloride, yellowish lakes of little stability are formed. It is also an interesting fact that pigmentschlarlach G (o-amidobenzoic acid, diazotised +  $\beta$ -naphthol-5-sulphonic acid) gives very good yellowish lakes, but which are still less stable. Of the three red dyes, permanentrot 6B, 4B,

and permanentorange, the first gives a blueish red lake of good stability, which gives good varnishing brilliant printing inks for artistic work. A dye which gives a very fiery red colour lake, which could be used with advantage for the printing of advertisements, is "Baumwollschlarlach extra," made by the Bardische Anilin und Soda-Fabrik, and it is, like the previous one, an azo-dye (amidoazabenzol +  $\beta$ -naphtholdisulphonic acid. "Eosinsäure I neu," made by the same firm, is also worth notice, as if precipitated as prescribed by the makers, gives an extraordinarily fiery blueish colour lake, which is not, indeed, very stable, but is considered more so than the other eosine lakes previously tested by me. Of the yellow dyes, alizarinegelb lake and the pigmentechtgelb G are very stable. The latter dye ( $\beta$ -sulphobenzoic acid diazotised + phenylmethylpyrazolon) gives, when precipitated, according to the maker's directions, a more stable product than pigmentechtgelb R (2-Toluidine-5-sulphonic acid diazotised + phenylmethylpyrazolon). It is well known that Indanthreublau is one of the most light stable dyes that we have. To make the lake Indanthreu S is rubbed up as fine as possible with the necessary medium. Unfortunately, it is not possible to obtain a fiery blue; in order to obtain a brilliant printing ink the dye should be precipitated from its solution on the medium. My experiments in this direction induce one to hope for this, and further results will be given.

E. VALENTA.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between September 10 and 15:—

**CAMERAS.**—No. 20,142. Improvements in photographic cameras.

Fabrik Photographische Apparate auf Aktien vorm R. Huettig and Sohn, Germany.

**PRINTING FRAME.**—No. 20,174. Improved photographic printing

frame for bromides or gaslight cut papers and postcards. Joseph Arthur Wilby, 11, Strawberry Lane, Armley, Leeds.

**GUN-FORM CAMERAS.**—No. 20,350. Improvements in gun-form photographic cameras. Emma Ella Crankshaw, 9, Tempest Hay, Liverpool.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 3d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**SQUEEGEES.**—No. 14,863, 1906. The invention consists in a new form of squeegee, which is constructed with handle with dovetail or other enlarged groove having rounded edges and a rubber blade with beaded edge of corresponding shape, but larger dimensions. The latter is inserted in the groove by stretching out the rubber until of less size and then sliding the handle

over it, the blade securing itself, unaided by glue or screws, on assuming its normal condition. Three suggested forms of the squeegee are shown. E is the rubber strip and B a strengthening piece. The handle may be made in one piece. The Thornton-Pickard Manufacturing Co., Limited, Altrincham, George Arthur Pickard and Frank Slinger.

**FILM AND PLATE CHANGERS AND DEVELOPERS.**—No. 17,553, 1905.

The specification describes mechanism for the transference (in daylight) of plates or films from an exposing chamber in the camera to a chamber for development and fixation on the spot or for subsequent development in a dark-room. The apparatus may be adapted to any construction of camera. If of the magazine pattern the carriers or sheaths must be open at one edge or side, and in the top part or side of the camera facing the open edges of the carriers is a slot so adjusted as regards position that this slot exactly corresponds with the position of one carrier, preferably that carrier standing up foremost in the camera, or opposite the lens, the slot being provided with a door or shutter opened or closed on the inside. The slot may be disposed laterally on the front, rear, or in the side in case it is desirable or only possible to transfer the plate together with its carrier after it has fallen. The plate receptacle may be connected or disconnected with the slot by means of a sliding piece, or spring attachment, so that a plate may be passed to or from the camera. William Fraser Claughton Kelly, 22, Winchendon Road, Fulham, and John Arthur Bentham, 51, Claverton Street, London.

**WINDING PAPER ROLLS.**—No. 4,697, 1906. The invention is intended to apply to photographic rotary printing machines, and relates to the securing of the paper web to the winding reel. In place of a ribbon attached to the cross-bars of the reel and to a lever clamp which grips the end of the paper, two lateral cords, a, b, or like flexible means, are employed, connected to the ends

of one of the cross-bars, c, of the reel, the clamping-bar, d, to two clips, e f. This latter connection is detachable, with hooks, or similar means, being used to connect the gripping means to the cords. By this arrangement, in case of need,

gripping means may be detached from the paper web, and drawn out laterally, and then fixed to the two ends of the web which is to be further wound up. George Bluen, 130, Leipzigerstrasse, Berlin.

**NUMBERING NEGATIVES.**—No. 20,787. The invention is an apparatus for numbering a negative at the time of exposure, and unknown to the sitter, and consists in arranging a carrier for consecutively numbered cards, in such a way that on a plate being exposed the carrier moves the number up against the plate, that the respective number is produced on the plate when developed. Howard Cumming Hitchmough and Harry Charles Moore, 101 and 103, Dale Street, Liverpool.

**STORAGE BOX.**—No. 20,204, 1905. The box is intended for the storage of sensitive paper and plates, and is constructed, as shown in the figure, so that the upper case a forms the lid of the lower

case b, there being a double hinge permitting the lid d of a to be raised on the case-form lid of b. Charles Edward Dodsley, 47, Shrewsbury Road, Oxtou, Birkenhead.

The following complete specification is open to public inspection before acceptance, under the Patents Act, 1901:—

**PHOTOGRAPHY.**—No. 14,072, 1906. Ippers.

**WORTHING Camera Club.**—The second annual open exhibition of the above club is fixed for February 25, 26, 27, and 28, 1907. Entries close on Saturday, February 16. The secretary is Edmund F. I. Crouch, 11, South Street, Worthing.

## New Apparatus, &c.

**Mercury-Vapour Lamps.** Made by Schott and Genossen, Jena. Sold by Isenthal and Co., 85, Mortimer Street, London, W.

The introduction of the mercury vapour lamp last year attracted a good deal of attention at the time, and photographers were fully informed of its possibilities by the series of articles from the pen of Mr. William Gamble, which appeared in our columns, and are quoted in an abridged form in the current *ALMANAC*. From America, the country of the first manufacture of the lamp, came the first records of its behaviour in the photographic studio, and that clever photographer in New York, Mr. Pirie Macdonald, was among the first to

give it his unqualified approval and to affirm its capability to respond to all the needs of a photographer having his studio in the heart of a great city. Since that time considerable experiment has been made in the construction of the lamps, and as one result thereof we have the issue of a new lamp of this type from the celebrated glass works of Schott and Genossen, at Jena, the factory, as most of our readers know, which supplies the raw materials to the optical firm of Carl Zeiss. The new mercury-vapour lamp is the outcome in the first instance of the application by the Schott firm of the new glass recently invented by them, and transparent to ultra-violet light. The mercury light being extremely rich in these rays, it is naturally desirable to transmit as large a proportion of them as possible, even though at present the lenses of ordinary photographic objectives are not transparent to a large proportion of these ultra-violet rays. However, the property of the new material of the tubes will be appreciated in process work—for which the lamps are, of course, suitable—much as certain new lenses, e.g., the "Actinolux," of Messrs. Y. Watson and Sons, transmit the ultra-violet rays. However, our

present interest is in the capabilities of the lamps for ordinary professional portraiture, and of that we are able to speak in very high terms. The most suitable equipment for a studio is a battery of three tubes, either 18 or 26 inches, supported on a standard which, with other mechanical accessories, is made in the Schott factory, and thus obtains the guarantee of first-class workmanship. Four of the 18-inch lamps can be worked off a 220-volt circuit (direct current) at a consumption of current of from  $2\frac{1}{2}$  to 3 ampères. The mounting of the lamps is such that they can be separated or withdrawn from each other as may be desired, thus permitting the photographer to diffuse or concentrate his light source in a precise manner and with the certainty of repeating the conditions at any future time. The price of the "L" pattern standard, as shown in the figure, is £8 10s. for two or three lamps, the lamps themselves costing from £1 to £1 5s. each. The whole construction of the outfit is workmanlike in the extreme, and the complete apparatus occupies but little space in a studio and is not in any way an unsightly erection. A special type of lamp standard is supplied, to which several ordinary incandescent lamps are attached, in order to counteract the characteristic effect of the mercury light. This they do quite effectually by providing the necessary red rays. The apparatus can be seen at Messrs. Isenthal's establishment in Mortimer Street, near to Regent Circus.

A new mercury-vapour lamp is being placed on the market by Messrs. O. Sichel and Co., of Bunhill Row. It is being shown by Messrs. Sichel at the Royal Photographic Society's Exhibition, in a form for printing purposes. We shall give further particulars of the lamp in a later issue.

**The Schroeder Studio Flashlight Apparatus.** Sold by Friedrich Schroeder, Brandenburga Havel, Germany.

When we visited the studio of Herr Dührkoop in Hamburg some months ago we saw in use a portable flashlamp, of which Herr Dührkoop informed us very considerable and effective use was made by him, both in the studio and for "at home" work. We have since learned that the lamp in question is the invention of Herr Schroeder, a professional photographer of Brandenburga, by whom it is now placed upon the English market through the houses dealing with professional photographers. Herr Schroeder has shown us a number of collodion prints of the very highest technical quality made with his lamp, in the studio and in his sitters' houses. In most cases the magnesium light alone was used, but Herr Schroeder is a strong supporter of the Puyo idea of employing daylight as an auxiliary to the flash or vice versa, and by this method has obtained results which could not have been obtained by either source of light used alone. The lamp consists of a combustion chamber of fabric, which encloses the smoke. The powder is placed upon an ignition plate, which forms the top of a small box containing the battery and magnetic apparatus which actuate the percussion cap igniter. The electrical connection permits of the ignition of the powder instantaneously, not only by itself—the lens being left open—but also at the same moment as the shutter of the camera; the one release actuates both at the same moment. Further, the shutter can be opened and an exposure be given by daylight of sufficient length to provide any softening effect which may be desired, and on pressing the button the flash is made and the shutter immediately closed. The mechanism thus provides for all practical requirements, and it says much for the apparatus that it is the outcome of Herr Schroeder's own professional work. The price of the whole outfit (which may be carried by the photographer) is six guineas.

**Christmas Motto Mounts.** Sold by Marion and Co., 23, Soho Square, London, W.

Anyone who may have nursed the delusion that a few fine days might still be enjoyed before the winter sets in will receive a mild shock by hearing that Messrs. Marion are issuing catalogues and samples of their series of Christmas mounts. We hope, however, that the circumstance is an instance of their foresight and enterprise rather than of the immediate decline of the year. Certainly they are the first of the mount publishers to apprise us of their new designs and issues for the approaching Christmas trade. The list is a long one, running to twelve quarto pages, and we have some difficulty in preventing ourselves from exceeding the limits of space in selecting a few cards for special mention and approval. L 152 and L 75 are two cards we like. They take the postcard size of print, and are neatly made in an "impressed" card, with deckle

edges and a lettered motto. L 54a is another neat style, in board of imitation canvas. L 54b is a single folding card, in imitation grey canvas, with green seal, whilst L 88 provides space for two 1½ in. circle prints, and bears the motto, "A Happy Christmas, and Look Forward to Many More." Messrs. Marion's list and sample packets (the latter 2s. and 5s.) may now be obtained.

A new issue of the Barnet ortho plates reaches us from Messrs. Elliott and Sons, Barnet, by whom increased rapidity has been imparted to the emulsion, an improvement to the plate, which should be appreciated during the autumn and winter season. We have found the plates capable of giving excellent results from a variety of outdoor subjects, including a range of autumn browns. The plates should be fully developed—the point is one on which the makers lay special attention—and if this is done the gradation of subjects in which strong colouring occurs is a kind which indicates the possession of excellent orthochromatic properties.

#### CATALOGUES AND TRADE NOTICES.

MESSRS. HARRINGTON BROS., 4, Oliver's Yard, City Road, London, E.C., send us their latest wholesale list of photographic chemicals.

### New Books.

Sir Benjamin Stone's Pictures—Records of National Life and History, Vol. I. and II. (London: Cassell and Co., Ltd. 7s. 6d. each).

These two collections of photographs by the President of the National Photographic Record Association must represent a very small fraction of the photographic work which Sir Benjamin Stone has prosecuted in season and out of season whenever the opportunity afforded. Yet the subject matter of the volumes, "Parliamentary Scenes and Portraits" (Vol. I.), and "English Festivals, Ceremonies, and Customs" (Vol. II.), could hardly have been more widely chosen with the object of interesting the public. The scenes and characters upon the stage at Westminster—be the performance comedy or farce—hold the public mind, and Sir Benjamin Stone's very factual full-length portraits of members of the House, posed on the Terrace, with the full light of the river beating on them, are more interesting than many presentments of these gentlemen made in a studio. "It is," as Mr. Michael MacDonagh ironically writes in an introduction, "the real man, with all his natural perfections crowding thick upon him, that we see." The second volume presents records of a large number of the fairs and festivals which still survive—chiefly in the rural districts of England—from the most ancient times. Sir Benjamin Stone, and those who have helped him, should receive the thanks of all who value the preservation of our characteristic customs and festivals, some of which take place only once or twice in a lifetime.

Each photograph is accompanied with a few words of explanation or comment, and the volumes thus become a source of continual entertainment in leisure hours. It is to be hoped that they will also stimulate the photographic record which the survey associations systematically, and many individuals and societies, are carrying out.

An international lantern-slide competition will be held by the Association Belge de Photographie, Brussels. It closes October 15, and slides competing for the three prizes should reach the Palais du Midi on or before that date. The slides will be judged by arc light. The Belgian Society are also holding a competition for stereoscopic transparencies.

PHOTO-SECESSION Exhibitions.—The second series of exhibitions at the Little Galleries, 291, Fifth Avenue, New York, will begin November 1. The first exhibition is to be devoted entirely to members' work. Every member has the privilege of having at least one print hung. It is preferred that prints be unframed, but mounted on mounts 14 by 22 inches; these conditions are not compulsory. This exhibition will be followed by monthly exhibitions of American and foreign work.

## Meetings of Societies.

#### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
29 Oct.	Hull Photographic Society .....	Outing to Pauli.
1.....	Southampton Camera Club .....	Slide Criticism Competition.
1.....	South London Photo. Society ..	"Composition and Effect in Pict. Photography." G. J. T. Walter.
1.....	Luton Camera Club .....	"Lantern Slide Making."
1.....	Bowes Pk. and Dis. Ph. Soc. ...	"The Optical Lantern, and How to Work It." Mr. C. Roberts.
1.....	Lancaster Photo. Society .....	Members' Lantern Night.
2.....	Manchester Amat. Photo. Soc.	"On Mounting Photographs for Exhibition Purposes."
3.....	Woodford Photo. Society .....	Affiliation 1906 Prize Slides.
4.....	London and Prov. Photo. Assn.	Annual Supper at the Hotel Bolo.
4.....	Hull Photographic Society ...	27, Gerard Street, W., at 7.30. General Meeting.

THE BRISTOL PHOTOGRAPHIC CLUB held a most successful dinner at the Royal Hotel last week, the function being intended as preliminary to the big open exhibition which the club has organized for October 6. A pleasing incident of the evening was the presentation of an aneroid barometer to the late hon. secretary, Mr. W. W. Smith, as a mark of the members' appreciation of his services. Mr. M. B. Fowler, F.C.S., presided.

## Commercial & Legal Intelligence

A BOGUS CANVASSER. — Frederick George Hardy, School Street, Tirphill, pleaded guilty at Merthyr Police Court last week to charges of obtaining money, falsely representing himself to be agent of Messrs. A. and G. Taylor, photographers, Cardiff. In the case the prisoner obtained from Elizabeth Jones, wife of the landlord of the Mount Pleasant Inn, Vochriw, and in the other case he obtained half a crown from Mary Ann Kinsey, a servant at the inn. Prisoner was in Messrs. Taylors' employment for a month, about three years ago, but since then he has had no connection with the firm, and had no authority to do any business on their behalf. He was sentenced to gaol for two months.

#### NEW COMPANIES.

STANDLEY, BELCHER, AND MASON.—This company has been registered with a capital of £6,000 in £1 shares (2,000 preference) to carry on the business of wholesale and retail chemists, manufacturers of surgical, photographic, and scientific apparatus, and to adopt agreements with S. Belcher and E. D. Mason. The subscribers are:—S. Belcher, E. D. Mason, E. K. Mason, Mrs. A. Belcher, E. R. Mason, W. E. Belcher, Mrs. E. Belcher.

G. J. KIRKUP, LTD., has just been registered with a capital of £500 in £1 shares (250 Pref.), to carry on the business of chemists, makers of photographic, optical, and other apparatus, and materials etc. The subscribers are: A. A. Thomson, Moray Cottage, Mussburgh, N.B., corn merchant; A. Watson, Cloth Market, Newcastle-on-Tyne, merchant; W. Tiffin, 127, Northumberland Street, Newcastle-on-Tyne, baker's manager; J. Reid, Spring Bank, Ryton, Durham, gentleman; R. Aitken, 35, Coniston Drive, Edinburgh, accountant; J. Scott, Brunswick Street, Edinburgh, accountant; A. Cunningham, c/o Raines, Clark, and Co., Leith Walk, Edinburgh, bookkeeper. No initial public issue. The number of directors not to be less than two, nor more than three. The first are A. Thomas, A. Watson, and W. Tiffin. Qualification, five shares. Remuneration as fixed by the company. G. J. Kirkup is the secretary and manager. Registered office: 9, Westmorland Road, Newcastle-on-Tyne.

## Correspondence.

- \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A HINT TO REFLEX CAMERA MANUFACTURERS.

To the Editors.

Gentlemen,—Having searched the pages of the "Almanac" in vain for my ideal reflex camera, I make bold to offer a suggestion for the improvement of this most valuable of all types of hand cameras, which, if added to the splendid instruments made by the leading manufacturers, would not only add enormously to their efficiency, but would render them all that the most exacting could desire. One finds plenty of such cameras with long extension, revolving back, and rising front, all of which movements are indispensable, and some have in addition a side-sliding movement which is quite a superfluous and unnecessary complication on such cameras, being indeed seldom, if ever, needed on any reversible back camera at all, except, perhaps, for copying; but one looks in vain for a reflex with a swing back. The probable reason for this is that this movement may be impossible to incorporate in a camera of this type; at least during six years I have given careful thought to the subject, and I have failed myself to design a swing back and focussing glass that would move in unison.

But at the very outset of my experiments a way of solving the difficulty occurred to me, and five years ago I had a reflex camera built to my order and specification by a mechanic in America, where I was at that time, which served my purpose and requirements perfectly. The camera has a double swing front—i.e., the front board pivots at the centre on an axis, and the lens can thus be tilted up or down.

Now, apart from the value of this movement in architectural work—for the effect of swinging the lens is exactly the same as swinging the back—let me point out its untold value in ordinary instantaneous work, or in press photography. Naturally, you always try to get a little elevation if you can (on, let us say, such an occasion as some public event in the streets), both to secure better perspective and to get above the heads of the crowd; and, given such a slight elevation, the man whose reflex is provided with a swing front can completely eclipse the efforts of his confrère whose camera is not so fitted.

Perhaps the weather is bad and the chief subject moving rapidly; the use of a small aperture is impossible, yet with a large stop only a portion of the picture can be got into focus. Now just tilt the lens out at the top a bit—i.e., tilted looking downwards, and instantly even at the full aperture of the lens (if the focus be not too great), say, a 7 inch at  $f/4.5$ , the whole field of view, from the heads of the people immediately below you to furthest infinity, comes into sharp and clear focus, and the effect, as you see it on the ground glass in the top of the camera, corresponds exactly with that on the plate. By this simple device the man whose lens is not faster than  $f/8$  can secure a result beyond the power of the other man, no matter how rapid his lens, if his camera front be rigid, for in order to secure a corresponding depth of focus the latter would have to stop down to  $f/16$  or  $f/22$ . During the last two years hundreds of photographs of Japan, Manchuria, and the Russo-Japanese War, which have appeared in the English, American, and Continental illustrated weeklies and magazines, under the copyright of the H. C. White Co. were made by me, and in every instance all instantaneous pictures were made with a camera fitted with a single swing only—i.e., the lens tilts out at the top only as that is the movement most required. Also the large series of pictures of Japan, Korea, and Manchuria, with which Underwood and Underwood flooded the English press at the beginning of the war, were made by me with such a camera for the most part, as, anticipating the war, I travelled through those countries before the war began.

Pictures of India, Burma, and Ceylon appearing from now on in the English papers, under the H. C. White copyright, will show what can be done with such a camera, as all moving subjects, and

many stationary, which I photographed in those countries, were made with this reflex.

The swing front presents little difficulty, and in my present cameras is operated by a milled head at the side. It does not interfere with the use of a rising front. I would suggest to the manufacturers that instead of fitting such cameras with useless side-sliding fronts, they should turn their attention to devising a front that would not only swing vertically, but horizontally, as well. Every experienced worker knows the enormous value of the side-swinging back at times—for instance, when photographing obliquely down a street or side of a building. By the use of the side-swing on such occasions the use of a much larger aperture is rendered possible.

These remarks may rouse the cry of "distortion." I can only say that in hundreds of photographs so made I can notice none. In any case a little distortion is much better than a badly blurred picture. The manufacturers who put a well-made half-plate reflecting camera on the market embodying the triple movement of rising front and vertical and horizontal swinging lens, will secure my order at once, provided the camera has the usual qualifications of long focus and reversing back as well, and certainly no press photographer could afford to be without it once the instrument is obtainable.

These swing movements are equally useful in getting foregrounds and prominent objects at one side of the plate into focus in landscape work, and once having learnt their full value, one can never be really happy with a camera which does not embody them. I sincerely hope these remarks may induce the British manufacturer to give us this ideal reflex the coming year.

I enclose a few sample prints showing in high speed and medium speed work objects from nine or ten feet to infinity in sharp focus.

H. G. PONTING, F.R.G.S.

c/o Chartered Bank of India, Yokohama.

[The photographs, all of which are evidently taken from a slightly elevated standpoint, have both foreground and extreme distance in sharp focus.—Eds. B.J.P.]

### COLOUR-PRINTING IN ENGLAND AND ABROAD.

To the Editors.

Gentlemen,—I cannot see that Mr. Tilney's further letter to you helps matters in the least. I am not concerned to deny that some colour engravings are imported into England; the object of my communication was to rebut Mr. Tilney's accusation that the whole blame for this rested with the English photo-engravers. I assert, and offer evidence for my assertion, that this is due to many causes; and, further, I state, without fear of contradiction, that English firms having men of equal experience will turn out work in every respect as good as foreign firms, and in less time. I admit that competent art direction may be desirable, but I should like to point out that this alone is not enough; two firms, to my own knowledge, priding themselves on their art direction, have never made a profit, and a third firm would be in the same parlous state if the art direction was not over-ridden frequently. No, I cannot help still feeling Mr. Tilney's reckless indictment of native photo-engravers as being incompetent to be unproven; I think I have already shown his speculation put forward to support this to be entirely baseless.

Mr. Tilney's playing upon words must be looked upon with regard to the argument as "pointless wit," and his calling me "Mr. Whatname" is also somewhat paltry, since I expressly stated the reasons for my anonymity, which I did not wish to preserve so far as Mr. Tilney himself was concerned.—Yours, etc.,

PHOTO-ENGRAVER.

### AN ASPERSION ON CANADA!

To the Editors.

Gentlemen,—In your issue of last week, beneath the head of "The Photographic Salon" and the division under "Tomfoolery," you say, "A child, and the lower half of its nurse, is sent by A. S. Goss—from Canada, and therefore the circumstance does not surprise us." Is there not some mistake in this? For, although I agree with the Editor's criticism, I would not go so far as to take it as a natural course that, coming from Canada, a photograph must necessarily be bad. Perhaps, indeed, Kipling's "The Lady of the Snows" has prejudiced the motherland, but I think that if a deputation of English photographers could visit the premier colony they would find, not only that there is a summer, but also that there are, at

least, one or two photographers whose standard approaches that of the critics of the Old Land.—I remain, yours sincerely,

NUGENT M. CLOUGHER.

36, Ridgmount Gardens, W.C.

September 24, 1906.

[We are afraid it is useless to comment on our critic's sentence.—Eds. B.J.P.]

#### THE BISULPHITE FIXING BATH.

To the Editors.

Gentlemen,—For years the acid fixing bath has been so generously damned by various photographic authorities that it is gratifying to find MM. Lumière devoting time to its investigation and giving it their support. Their reference to the use of bisulphite in the fixing bath would, however, give one the impression that its use in this direction was of quite recent introduction, whereas it has been in use for upwards of twenty years. When eikonogen became popular as a developer in 1889, an acid fixing bath, containing bisulphite of soda, was recommended by the Actien Gesellschaft für Anilinfabrikation, who apparently owed their knowledge of it to a formula by Dr. Hermann Gunther.

Bisulphite of soda, as an addition to the fixing bath, was first advocated by H. B. Berkeley; it was also suggested in these pages by the then Editor, W. B. Bolton, for use with films, but he used it as a separate bath between development and fixation.

Gunther pointed out that when using bisulphite of soda in the fixing bath an alum bath might be used without fear of any precipitation.

When Cramer introduced his acid fixing bath I used it for some time, but gave it up for the simpler bisulphite bath, which I have used and advocated for the last sixteen years. Probably, now that it has received the hall-mark of MM. Lumière's approval, it will win its way to popular approval.—I am, Sirs, yours faithfully,

Sidmouth.

G. T. HARRIS.

#### AFFILIATION NIGHT AT THE P.P.S.

To the Editors.

Gentlemen,—Will you kindly accord me space to announce that the annual gathering of members of the affiliated societies will be held (by permission of the Council of the R.P.S.) in the New Gallery on Friday next, 28th inst., at 7 p.m., when the committee hope to see a large number present.

Members of societies will be admitted on showing their Red Books, their friends on payment of 6d. each, *plus* a red ticket.—I am, yours, etc.,

A. R. F. EVERSHEED,

Chairman of Committee.

6, Daysbrook Road, Streatham Hill, S.W.

September 22, 1906.

#### THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—The usual holidays have prevented me from writing to thank Mr. Kenneth Mees for his explanation as to standard light, given in your issue of August 3.

There are one or two other points upon which Mr. Mees or Mr. S. E. Sheppard will kindly enlighten me, perhaps.

In a paper entitled "The estimation of the colour-sensitiveness of plates" (*PHOT. JOURN.*, March, 1906), on p. 112 occurs the following passage, when speaking of the standard acetylene light filter: "It let through far too much red, while the failure of the acetylene flame to supply sufficient violet and ultra-violet was insufficiently compensated. The only way in which this last defect could be set right was to darken all the rest of the spectrum, etc." My point is that the acetylene light, as adopted by Messrs. Mees and Sheppard, is not comparable to diffused daylight, because of its deficiency in violet and ultra-violet. Surely the suggested remedy, namely, the darkening of the rest of the spectrum, is a parallel case to the Irishman, who, finding his blanket too short, cut a bit off the top and sewed it on to the bottom.

This disadvantage of the acetylene light is also proved by Messrs. Newton and Bull in a paper entitled "Orthochromatic plates and sensitizers" (*PHOT. JOURN.*, Jan.-Feb., 1905, p. 17), where it is said: "Although it is a disadvantage in work of this kind not to be able to use daylight or arc light, the only result observable

in using a light less rich in the shorter wave-length, is the subduing of the photographic effect of the blue, violet, and ultra-violet, etc." (The italics are mine.)

If we subdue the photographic effect of the shorter wave-lengths, surely for scientific measurement we reduce the speed of the plate; if we do not, then an ordinary plate behind Eder's potassium chromate screen should give us the true inertia also.

The other point which worries me from a practical point of view is the question of fog. In the thesis by Messrs. Mees and Sheppard for the degree of B.Sc. (*PHOT. JOURN.*, August, 1905, pp. 296-297) there appears a "note on fog," which concludes thus: "Obviously, fog increases faster in unexposed film than in the exposed; it is desirable, therefore, for photo-chemical investigation, to have an emulsion which does not give fog-density higher than 0.15 to 0.2, even on infinite development."

Now, if I want to apply Messrs. Mees and Sheppard's work to the practical testing of commercial plates for speed, having no control over the fog density, how can I rely upon the readings? For instance, taking the reading of a certain plate I find that deducting a fog density of 0.22 the speed is 200 H and D, but as the fog increases more upon the unexposed than the exposed strip it is obvious that this reading is too low. If I do not deduct the fog the plate reads about 400 H and D. What, from a practical point of view, am I to do?

I trust that Messrs. Mees and Sheppard will not think I am just quibbling, but these are points which are stumbling blocks to me, and I have only taken the subject up because I want to really learn it if I can, though I am handicapped by my ignorance of mathematics.

May I also ask Mr. Ferguson or Mr. Mees to explain how the factor 0.4186 is obtained in the explanatory letter by the former writer in your issue of July 27, p. 598. It occurs in the example worked out for finding a development factor = 1 when K and  $\gamma_{\infty}$  are known.—Yours faithfully,

London, E.C.

ARTHUR GASCOIGNE.

PROCESS INSTRUCTION IN MANCHESTER.—The prospectus of the department of photography and printing crafts in the Municipal School of Technology, Manchester, reaches us from the director, Mr. Charles W. Gamble. The various courses of instruction are planned to extend over two years and to provide a thorough training in the theory and practice of photography. The syllabus of this two years' course is as follows:—First Year:—Chemical: The methods of making solutions for ordinary use; preparation of special substances; making collodion; preparation of sensitive papers; development; orthochromatising dry plates. Optical: The simple examination of lenses; determination of focal distance and effective angular aperture; diaphragm values; making and testing light filters for various purposes. Mechanical: The examination and testing of apparatus, as cameras, dark slides, stands, exposing devices; camera manipulations. The Action of Light on Sensitive Surfaces: Testing the sensitiveness and gradation of photographic plates and papers; testing the colour sensitiveness of photographic surfaces; the use of colour charts and colour sensitometers. The Preparation of Negatives for Printing: Methods of intensification and reduction; printing processes; methods of printing by daylight and by artificial light; toning methods; development of various kinds of sensitive papers. Second Year:—The photographic camera and its accessories; lenses for different classes of work; camera images; manipulations with cameras and lenses; lighting; the various effects in the appearance of objects produced by different conditions of lighting; range of gradation in light and shade; exposing and the conditions which govern the exposure given to sensitive surfaces; development and after processes; the preparation of negatives for printing; production of prints; relation of the negative to the printing process; typical printing processes; albumen, collodion and gelatine papers; the platinum and carbon processes; bromide papers; mounting and finishing prints; the production of enlarged negatives and prints; reproduced negatives and transparencies; lantern slides. In addition there are full lecture and laboratory courses of instruction in photo-mechanical work and series of practical demonstrations in portraiture, silver platinum and carbon printing, negative retouching. Those in the Manchester district who are thinking of adopting any of these crafts as a livelihood should obtain the prospectus of the school or consult Mr. Gamble as to the best course of procedure.

## Answers to Correspondents.

**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.**

**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.**

**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

### PHOTOGRAPHS REGISTERED:—

W. R. Jack, 82B, Lowther Street, Carlisle. *Photograph of the Carlisle Cathedral Copes. Photograph of the Bishop Bardsley Memorial.*

Mythb & Carey, 38, Fore Street, Bridgwater, Somerset. *Photograph of the Bridgwater Swimming and Water Polo Club.*

Madge, Frogmore Buildings, Abergavenny. *Photograph of the Rhymney Royal Male Choir.*

W. Ralston, 259, Rauchlehall Street, Glasgow. *Photograph of the Uddingston Cricket Club, First Team, 1906.*

Lydney, 24, Oxford Road, Manchester. *Photograph of the Picnic of Affleck and Brown at Windermere.*

A. Crook, Sandlea Villa, Datchet, Bucks. *Photograph of the Interior of St. Mary's Church, Datchet.*

G. Browne, 12, Sarsfield Quay, Dublin. *Photograph of Sergeant Doubleday, Middle Weight Wrestling Champion of Ireland.*

T. B. Robinson, 185, High Street, Homerton, London. *Photograph of Clapton Orient Football Team, 1906-7.*

T. Abery, 17, High Street, Bullth Wells. *Photograph of the Lord Mayor of London, High Sheriff of London, Mayor of Swansea, Mayor and Corporation and Officials of Brecon, and the Leading County Gentry. Photograph of Mamie Panquet held at the Castle Hotel, Brecon, in Honour of the Lord Mayor of London's Visit to Brecon.*

**COPYING, ETC.**—(1) In the course of my work I have to copy some portraits which appear to be sepia platinotypes. I find it difficult to obtain a negative on rapid plates which give a print equal to the original. Is it correct to use a fast plate, or should I use a slow plate, such as a "process," in order to obtain a negative which would give a rich plucky print? (2) Can you give me a toning formula for silver paper which will give a black or nearly black image while keeping the paper perfectly white?—A. R.

(1) We should advise you to use a plate of "ordinary" rapidity, and give a very liberal exposure. A print of this colour requires plenty of exposure, and we suspect your failure has arisen from insufficient attention to this point. (2) By over-printing, toning in the usual way, and then reducing the prints with weak persulphate solution (5 grains per ounce), you will get a very black colour equal to the results with the platinum bath.

**RETAIL.**—If you mean half-tone blocks, we are afraid we cannot. The process requires greater space than we can give it. You should study a text-book on the subject, such as Wilkinson's "Photo-Mechanical Processes." A paragraph on making photogravure copper plates appeared on page 743 of last week's issue.

**RELATINED HALF-TONES.**—Can you tell me how the enclosed postcard is gelatinized? I have tried the ordinary process of floating a half-tone print in gelatine, but it does not leave a gloss like enclosed card. Would the cards require to be sized first?—J. M.

The usual method is to float on the hot solution of gelatine and to immediately pass through rollers. An ordinary mangle, with a couple of ferrotype sheets, between which the cards are passed is used, to our knowledge, effectively for this work.

**ADDRESS WANTED.**—Can you recommend me to a first-class ivory miniature artist in this district?—W. B. YOUNG.

Addresses of those who produce ivory miniatures will be found in the advertisement columns of the JOURNAL. It is against our rule to specially recommend any particular advertiser's work or goods.

F. S.—If you made the enlargement from the single picture, and the copyright in it was not registered at the time you made it, you have not infringed the law. If you had made your reproduction from the portrait in the combination picture, the case would be different, because the Act makes it illegal to reproduce any portion of a copyright picture. If the man registers the copyright in the single picture now, he cannot proceed against you for what you have done.

**ENAMELLED DISH.**—I have an iron enamelled dish used for clearing platinotypes; enamel has come off partly. Can you recommend me a white enamel to touch it up? 2. I shall be obliged if you could give me address of maker of Whatman paper, or wholesale agent? Also vellum.—INQUIRER.

1. Aspinall's enamel is good for the purpose. See that the dish is thoroughly dry before it is applied. Two or more coats, thinly applied, may be necessary. 2. Whatman's paper may be had from any of the large dealers in artists' material. Vellum paper may be procured from such houses as Marions', Houghtons', etc. If they do not stock it they will doubtless procure it for you.

**ADDRESS WANTED.**—I would be much obliged if you will kindly give me through the medium of your valuable journal a name and address of a firm who are willing to let on hire dresses and wigs of different periods; my purpose is genre work.—ENQUIRER.

Fox, Theatrical Furnisher, Wellington, Street, Strand.

**STUDIO QUERY.**—1. I enclose a rough plan of a photographic studio I intend building in Madrid. It is to be situated on a terrace rising above all the surrounding houses. The walls marked with continuous lines cannot be altered, as they form part of the façade of the building, and all the little windows are required to keep the studio in harmony with the style of the rest of the building. But these, of course, can easily be curtained. The walls marked with dotted lines can be built in any way I desire, as also the ceiling, but they cannot be moved to alter the size of the studio in any way. Under these circumstances I should be very much obliged if you would trace out for me a cross-sectional elevation of what you would consider the best studio that can possibly be built on the site, giving as far as possible all the dimensions. "A" is where I propose putting a glass door. I should also deem it a great favour if you could give me any hints as to the kind of glass to put in, the colour the studio ought to be, and such items that go so far to make a complete success of the whole thing. 2. I also have to fit up a dark-room, and, so far, I have failed to secure any book dealing in any way with an ideal dark-room. Does such a publication exist?—C. P. A.

1. We should advise you to build the studio so as to utilise the light on the north side. This will give you a studio about eight metres long and five wide. About a metre and half, or a little less, at either end of the side, may be made opaque, and the rest glass. The same will apply to the roof. Ordinary plain glass will answer, unless the side is overlooked, then fluted, or rolled plate, may be used. For the colour, a rather dark French grey is as good as anything. We would suggest that you get Boias' book on Studio Construction, published by Marion and Co., Soho Square, W. You may get some hints that will be useful to you. 2. "The Photo-Miniature," No. 33 (Dawbarn and Ward, London), but most persons design the dark-room to suit their requirements—according to the space at their disposal.

**INTENSIFICATION WITHOUT METALLIC SALTS.**—In your issue of April 1, 1904, No. 2,291, Vol. LI., I read an article by Mr. J. S. Teape on "Intensification without Metallic Salts," and it has occurred to me to ask if this process is one that is meeting with favour amongst experts, as against the other processes. I have not noticed any further contributions in your journal on the subject, but if there have been, I should be glad to have the dates on

which they appeared. The process suggests great possibilities in the improvement of negatives, and I am sure many of your readers would appreciate an article, such as the one that appeared, giving the further result of experience, and experiment of this process. I may say I have made one or two trials of it with more or less satisfactory results—as an amateur—but I should be glad to hear from Mr. Teape or some other qualified contributor, as to the results of further experience of the process.—T. C.

You will find a resumé of the recent work on pp. 792-6 of the "Almanac."

**UNCEMENTING LENS.**—I wish to dissolve the Canada balsam in the front combination of a whole-plate portrait lens. Please say best and quickest way, as the lens is in constant use.—MANCHESTER.

Remove from the metal mount and place in some warm water contained in a saucepan on the bottom of which a few thicknesses of blotting paper or flannel have been laid. Add hot water gradually, until at last the whole is as hot as the hand can bear. When this is the case quickly apply a twisting movement to the upper lens, holding the lower one. They should slide apart. If they do not, the only thing is to make hotter and try again.

**VARIOUS.**—1. Where can I purchase the Bolcliffe or Bowcliffe midget camera and lens?—ANXIOUS.

1. J. Bilcliffe, Manchester, S.W. 2. It is against our rule to draw distinctions. If you compare the recent descriptions of the apparatus you can surely draw your own conclusions. 3. Better estimate the cost yourself from the lists of Fallowfield, the Tress Co., Sharp and Hitchmough, or Bolcliffe.

**FORMULÆ.**—Could you inform me whether it is possible to buy a book of up-to-date formulæ, such as developers for bromide paper, toning process for some, in fact, any dark-room recipes; where such a book is obtainable, and cost of same?—NATALIA.

The "British Journal Almanac," or the "Figures, Facts, and Formulæ of Photography."

**H. BURNE.**—The Platinotype Co., 4, Bloomsbury Street, W.C.

**A. COPYRIGHT QUESTION.**—In February last we copyrighted the enclosed combination of photographs, which we've taken individually, and each man remunerated for his trouble by receiving free copies. Now, a local photographer has received an order from one of these men (marked with an X), who handed him either the picture we gave him, or one he bought of us, printed separately, as also enclosed. Can we stop the photographer copying this separate picture, which is also in the combination copyrighted, but was not copyrighted independent of the combination? Your kind reply will oblige.—CHARLES KNIGHT.

Certainly not. You cannot make a dozen different subjects copyright by mounting them on one card, copying that, and then registering it as one picture. As the enlargement was made from one of the subjects which was not registered, the one who did it was quite within his legal rights.

**EXECUTION OF ORDER.**—I photographed a group of twenty persons (12 x 10) to be presented to one of the persons in the group, which order has been completed. The others in the group require twelve copies, but the one who has received the present objects to me supplying them, because she does not like her expression, etc. She had nothing to do with the ordering of the group, and has paid me no money. Can she stop me or sue me, etc., if I supply photographs to the other persons in the group, who think it a splendid photograph?—RODINAL.

We do not see how you can be prevented from executing the order, merely because one in the group does not like her expression—particularly as the group was not taken to her order.

**FORMULÆ WANTED.**—1. Will you kindly give me a good formula for washed collodion emulsion, and how is the emulsion washed? Would there be any difficulty in making small quantities, from 10oz. to 20oz., and what chemicals are used as sensitising dyes to increase the speed of the emulsion? I require the emulsion for black and white copying only. I refer to similar dyes as

used with Dr. E. Albert's emulsion. 2. If not asking too please give me a formula for matt varnish.—OLD READER.

1. There is no difficulty in making the quantity of emulsion mention. But space is too limited in this column to working details that would be of any value to one apparently ignorant of the subject. Formulæ for washed emulsion found on pp. 968-969 of the "Almanac." We should add to obtain Abney's work, "Photography with Emulsion Klein's "Collodion Emulsion." They will give you necessary information. 2. Sandarac 90 grains, mastic 20 ether 2oz.. When dissolved, add benzol from ½oz. to according to the grain desired. (See page 962 of "Almanac.")

**OLD LENSES.**—I shall be much obliged if you will give me some of the maker and value of the two following lenses I have had given me. Each is like the present-day trait lens, each has a rack and pinion, no stops, diameter of lenses about 2½in. to 3in. Front lens is a compound lens; back lens of each is a "separated compound" (a ring intervening). The only marks I can find are pencil the edges of the glass thus:—"Launn, Paris," "Mrs. O. The flange of the lens having the latter mark has engraved it "Voght." Would this be a forebear of Voigtlander's? donor tells me that his father was one who never spent a penny so as to get the best then obtainable, and he remembers one of the lenses cost £15, but cannot say which. CHILTON.

We can give no idea of the value of the lenses without seeing them. From the description, we should say that are ordinary portrait lenses of old French make, and have little market value now. Voigtlander's lenses always bear name in full, with a number, and address.

**MR. GEAR'S Classes in Photography.**—Mr. John H. Gear will conduct classes during the forthcoming winter at the Cripplegate tube, Golden Lane, on Wednesday evenings at 6.30, commencing October 3, and at the Croydon Polytechnic, Thornton Heath Thursdays, commencing October 11. In connection with each are special practical classes for bromide enlarging, lantern making, etc. The course of lectures includes exposures, neg making, development, printing, mounting, hand cameras, their and misuse, combination printing, intensification of negatives, bromide enlargements, architectural work, orthochrom work, flashlight, platinotype printing, carbon printing, enlarging negatives, and lantern slides.

**THORNTON-PICKARD 1906 Competition.**—We are reminded that competition, in which £100 is offered in prizes, closes October 1. The necessary entry form and prospectus will be sent at one application to the Thornton-Pickard Manufacturing Company, Altrincham.

**PLATINOTYPE Demonstrations at the R.P.S. Exhibition.**—Demonstrations of platinotype, including the new "Japine" paper, given daily at 4.30 at the Platinotype Co.'s stall and at 7.30 on evenings when the exhibition is open.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears the best portion of the paper.

## SUMMARY.

The Cameron Exhibition closes to-morrow, Saturday, at 12.30.

On Thursday next an exhibition of photographs, chiefly portraiture, will open at the house of the BRITISH JOURNAL OF PHOTOGRAPHY. The collection is made up of contributions, each of one print, from members of the Professional Photographers' Association.

The Ozbrome Process.—We publish a full report of a lecture by the Rev. H. W. Dick, giving practical particulars of this method of printing carbon prints from bromides. (P. 785.)

Colour Photography.—Baron von Hübl recounts his experience of the Smith bleach-out paper for obtaining colour prints at one exposure from coloured originals. (P. 787.)

The behaviour of soda sulphite in conjunction with soda carbonate is the subject of two editorial notes, and two letters (from Mr. H. W. Bennett and from a Lausanne correspondent) will be found on page 798.

The movements desirable and attainable in reflex cameras is the subject of some interesting correspondence. (P. 797.)

The Royal Photographic Society's Exhibition.—Reviews of the professional, technical, and scientific, and trade sections appear on pages 788-791. The exhibition closes on October 27.

A lantern-slide printing-frame and a method of retouching negatives are amongst the patents of the week. (P. 793.)

Some advisory notes on backgrounds for the professional photographer appear on page 784.

## EX CATHEDRA

The  
"Almanac,"  
1907.

Our labours in connection with the forthcoming issue of the "Almanac" are approaching a conclusion, and the forty-sixth volume of this universal publication will leave our hands to pass through those of the printers and binders before many days have elapsed. The tasks of ourselves and our publishers will be lightened if all those who have any communications for the "Almanac" will send them immediately. Our own ability to review novelties in the way of apparatus is largely a matter of securing the articles in good time, and we would ask that all firms who have not yet done so would be good enough to place their introductions in our hands without delay. Our publishers ask us to say that the last day for receiving advertisements is Thursday, October 18.

\* \* \*

To Society  
Secretaries.

The pages of "The British Journal Almanac" being now in a state little short of that which will justify us to give the word to the printers to pass the whole edition to the machines, we shall be glad if all secretaries of societies will take notice of our second application for particulars of their societies, to be inserted in the directory which for many years past has been a feature of the "Almanac." Those who have mislaid the form upon which these particulars should be entered may have a second copy by return of post on applying to our publishers, Messrs. H. Greenwood and Co. We would also remind our secretarial friends that the fixtures arranged by them for the opening season will be cheerfully announced week by week in THE BRITISH JOURNAL OF PHOTOGRAPHY, if the card or programme is forwarded to us.

\* \* \*

Grants for  
Photographic  
Research.

In our correspondence columns this week appears a letter from Mr. F. A. Bridge, announcing, in accordance with a recent decision of the Council of the Convention, the willingness of that body to grant monetary aid to the carrying out of photographic research. The determination of the Convention thus to promote the progress of scientific and technical photography is of old standing, but has dropped out of notice of late years, doubtless owing to the lack of applications from those qualified to undertake research work of a kind likely to be approved by the Council. The conditions on which grants are made are outlined in Mr. Bridge's letter, and our hope is that the standing offer of the Convention will be noted by those able to carry out experiments which promise to be to the benefit of photography. If the Convention can

do the smallest thing towards fostering research in this country, it should earn the gratitude of all classes of photographers.

### The "Single Picture" Exhibition.

The collection of photographs by members of the Professional Photographers' Association is now brought together in the house of THE BRITISH JOURNAL OF PHOTOGRAPHY, and will be opened to visitors on Thursday next, October 11, at 10.30. We have been gratified by the response from members of the P.P.A. in all parts of the country, since the act of sending a print can be prompted only by the desire to further the end of ourselves in promoting the exhibition, namely, to afford an opportunity for photographers to see side by side the work of a large number of their fellows, such work being selected by the photographer himself as that which most correctly represents the output of his studio. The exhibits which will be visible at the little gallery at our offices until November 10, will be worth a visit, not only on account of the different styles of lighting which the photographs illustrate, but also for the demonstration of the effects obtainable by ringing the changes on the papers and mounting boards at the disposal of the professional. In this respect alone the exhibition can scarcely fail to stimulate the struggling professional to produce things which are better—and, we hope, more profitable. We are convinced that, under proper management, the latter will follow the former.

### Slovenly Work.

It is somewhat surprising that some photographers, who expend much time and skill in producing excellent work, are so careless of the way in which the pictures are finished and handed to their customers. One not infrequently sees excellent pictures considerably marred by bad mounting and spotting—the latter often not matching with the colour of the photograph, so that it is really as conspicuous as if the spotting had been omitted altogether. Bad trimming of the prints greatly detracts from the appearance of the picture, caused by the carelessness of the mounter, or possibly through the corners of the shape being worn or chipped. We were forcibly reminded of this the other day when looking at the specimens in the show case of a very high-class West End photographer. The pictures themselves were most excellent. They were trimmed oval and mounted on Cosway border mounts. The prints were very unevenly cut, and an attempt had been made to

remedy the unevenness with water colour, which was conspicuous, as it did not match the colour of the graph. We mention this case merely to illustrate some, even high-class, photographers neglect little in the final finishing of their pictures. Such omissions, when exhibited as specimens in show case, lead some observers to imagine that similar or defects may obtain in the work generally issued from the establishment.

### A Non-Staining Pyro Developer.

We regret to find that some errors crept into our paragraph last week on this subject (p. 763), and they may mislead those desirous of experimenting with the developers mentioned, with this opportunity of correcting them. The sentence referring to the old formula used (beginning in the line) should read: "Previously we used one-fifth of the first two ingredients in (a) and three-quarters (one-third) the quantity of carbonate." Further, the strength of the stock neutralised sulphite solution should be 4 oz. of sulphite and 1 oz. of metabisulphite in (not 40 oz.) of water. The new formula we recommend is made up by dissolving 160 grs. of pyro (or pyrox) ounces of stock solution, and then adding water to 20 oz. The alkali solution used with this contains soda carbonate in 20 oz. of solution. The old formula is so slow in its action, is made up by dissolving 16 pyro in 12 oz. of stock sulphite solution, and adding of water, to make a total of 20 oz. With this, the solution used contains 3 oz. of carbonate in the 20 oz. This old formula gives, in about five minutes, at a moderate temperature, a negative that is too thin for ordinary poses, but one that is not, perhaps, unsuitable for colour work. We have given this old formula partly on this account, and partly because it happens to be the formula with which most of our experiments have been conducted. As regards the colour of the image, there is nothing to choose between the two formulæ, but the new and more rapid one gives greater density in the same time. As regards ultimate staining and keeping qualities, we know the old formula to be all that can be desired, but our experience of the newer one being much shorter, we cannot yet speak so positively with regard to it. It should be explained that the restraining influence of the sulphite solution is all in the direction of retarding density, and does not seem to hinder the appearance of detail.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

### THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographer the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to draw the attention of advertisers to the fact that the LAST DATE for receiving orders and copy for advertisement in the "Almanac" is THURSDAY, OCTOBER 18.

short development gives thin negatives full of detail. Prolonged development gives as much density as can be desired. In the fifth line of last week's paragraph, "pyro of pyrax" is a printer's error for "pyro or pyrax." We have mainly used pyrax on account of its convenience, but comparative experiments with pyro have shown that both compounds act in the same way precisely.

#### Some Curious Effects with Pyro-Soda.

The formula we have recommended in a previous note has some peculiarities, and gives effects that are not common to pyro-soda developers. The pyro stock solution is pink, and the addition of the alkali turns it yellow. This mixed developer will keep for months, but, as before stated, sulphite deteriorates in the presence of alkali, and so the kept one-solution developer gives a stain which increases with the age of the solution, though the solution itself remains perfectly clean and transparent. A one-solution pyro-soda developer that keeps as well as this is certainly unusual. The next point is that if a developer is used for a number of plates in succession, after about the sixth plate it becomes milky and useless, but up to this time it remains perfectly clean and transparent, and is of a yellowish or amber colour. If this clean used developer is allowed to stand, it speedily becomes bright red in colour, but shows no deposit of any description for a very long time. There is no sign of the brown muddiness that generally characterises a used pyro-soda developer. The developed plates are put direct without washing into a plain hypo fixing bath, and this bath, of course, quickly acquires the pyro colour. At first it is a yellow brown, but on standing after use it becomes a rich ruby or port wine colour, and remains perfectly clean and transparent for weeks. After about two months a precipitate is formed, but the cleanliness and colour of the solution prior to that appearance are both remarkable. We are quite unable to explain these unusual effects, except on the assumption that the preservative sulphites used have uncommon properties. It is difficult to guess what the exact composition of the mixture of sulphite and metabisulphite may be, but it is certain that it has characteristics quite different from those of plain sulphite or metabisulphite alone. Its keeping properties show that it is essentially different, for it is serviceable for any purpose for which sulphite is used, when a solution of either of the separate ingredients has deteriorated so much as to be quite useless. A peculiarity of this mixed neutral sulphite solution is that it is generally yellow in colour. It is doubtful if it is so with perfectly pure sulphite, but with samples commonly supplied as such it is an obvious yellow, though no precipitate is formed.

#### "Globe" that does not "Roll On."

To those who are interested in the subject of prejudice as it affects progress, an article in a recent issue of the "Globe" will be found so full of entertainment that we reprint it on another page. The writer of this curious article appears as a critic of the two photographic shows now open. His criticisms will, perhaps, appeal to an octogenarian here and there about the country; but all present-day photographers will regard them with interest only as they afford a pleasant link with the past, calling up associations of the quaint antique. For this critic's point of view is that of one to whom the term "photograph" is synonymous with "silver-print." Consequently, upon everything in these shows not recognised by him as a photograph of this type he raves in a way that is highly diverting. Speaking of a few awful examples at the shows, the review says:—

"These things and a host of others make the show a painful disappointment to all sincere believers in the future of photography." Now, who are those sincere believers? We thought we were amongst them; but obviously this lonely critic makes up the total, because he alone has suffered "painful disappointment." Everybody else seems tolerably pleased both with present conditions and with the outlook. Certainly artists are; for they see that photographic processes rely more and more upon the very faculties that make the true artist in other mediums. The artist is invariably the readiest to grant the charm and quality in works such as are now publicly shown in London. The works are as far removed as the poles from the Great Exhibition—crinoline—waterfall—and—footbridge—type of thing that the critic of the "Globe" pines for, and they are only possible by "treatment"—a thing of which the Early Victorian was ignorant, and to which the artistic scope of the "Globe's" critic does not extend.

#### Industrial Alcohol.

On Monday last the Revenue Act of 1906 came into operation. This Act permits alcohol, upon which no duty is charged, to be used for manufacturing purposes. For years German manufacturers have been able to use pure alcohol, free of duty, while English ones have had to pay a heavy one on what they use; hence Germany has, hitherto, held a monopoly in certain things that require pure alcohol in their production—many of the coal tar colours, to wit, and other chemical preparations. Things that could be made in Germany at, say, sixpence the pound, could not be produced here for nearly five times that sum. Consequently, the business has gone to that country, to the loss of our own manufacturers. It is only, however, in cases in which no alcohol remains in the finished result that relief is given, the extent of the reduction being some 40 per cent. in the cost of the spirit. Before manufacturing can be undertaken with the alcohol in question, it will be the duty of the Excise to see that it is blended with 5 per cent. of wood naphtha, to render it nauseous to the taste, and save the interests of the Inland Revenue—and the publican. As the concession is only made where no alcohol remains in the finished product, we suspect that collodion users will not benefit much under the new Act. The 5 per cent. of wood naphtha would not be very detrimental in collodion, even for negatives, if the naphtha were fairly pure. At present methylated spirit contains 10 per cent. of naphtha, but that would not be a serious matter if a pure or refined naphtha could be employed, but that the Excise will not allow. All samples of naphtha have to be submitted to the Excise authorities before they can be used by the methylator, and if they are of too pure a nature they are rejected.

#### Works of Art and the American Customs Duty.

It is pretty generally known that the duty imposed on pictures imported into the United States is exceedingly high. Recently the well-known picture dealers here, Messrs. Agnew and Sons, sent a painting to America. It was invoiced at three thousand pounds, but the Customs appraised it at double that sum, which increase, under the American Customs laws, made the picture subject to seizure. The Messrs. Agnew appealed against the decision of the Customs authorities on the grounds that the picture was sold for £6,500 subject to approval, and that until all points of the argument had been fulfilled, the painting still belonged to them, and should be valued at the price they paid for it, namely, £3,000. We now learn, from a Laffan's telegram, that

Messrs. Agnew have been successful in their appeal. The excessively high duty levied by the American Government on works of fine art is the means of keeping much out of that country. It is stated that more than one American millionaire has a number of pictures, for which they have paid almost fabulous sums, practically, warehoused here because they will not consent to pay the exorbitant duty imposed by the American Customs.

### **The Spectacle Makers' Company and Opticians.**

\* \* \* The "Standard," in an article one day last week, under the sensational heading "Alarmed Opticians," discloses a remarkable situation. It may be remembered that last session a Bill was put forward by the Spectacle Makers' Company—one of the ancient City Companies—as regards the testing of sight, and it was read a first time in the House of Lords. It was then abandoned. On making inquiries, a representative of the "Standard" found that a situation had been created that not only affects the internal working of the Spectacle Makers' Company, but may affect other City Companies. It appears that, according to the Charter granted by Charles I. to the Spectacle Makers' Company, all members of the company must be connected with the profession of spectacle making, and must acquire a practical knowledge of the art. It now appears that the terms of the Charter have not been kept, for not one of the gentlemen forming the Court is in any way connected with the trade. For example, one is a newspaper proprietor, another a caterer, one a baker, one a fancy warehouseman, another a ship-owner, and others are engaged in other pursuits in the City. It is stated that the income of this Company is something like two thousand pounds a year. It is supposed to be used for the benefit of the craft, and opticians generally throughout the kingdom have protested against the Bill promoted by a body who have no practical knowledge of the trade. It is understood that the general body of practical opticians have drawn up a second Bill of their own, which will be presented when Parliament reassembles. The "Standard's" article has brought a rejoinder from the clerk to the Spectacle Makers' Company, controverting some of the statements, and this has been replied to by Mr. Chas. Hyatt-Woolf, the editor of the "Optician and Photographic Trades' Review." Other letters will probably follow, and there may be an interesting controversy on the subject and, possibly, the composition of other ancient City Companies.

### **BACKGROUNDS.**

THE background in portraiture has always been, and always will be, of the utmost importance, be the method of expression what it will. Whereas, however, the artist whose work is entirely creative can make any background he pleases, the photographer is entirely restricted by the number of grounds he can conveniently keep ready painted in his studio. The importance of the selection of this limited number of grounds cannot be over-estimated. They must, not only from an artistic, but a utility, point of view, be of such a character as to be readily used for various subjects. They must be quiet and unobtrusive, and, in the case of professional portraiture, not so distinctive as to be easily recognised. If, however, the function of the background to enhance and accentuate the subject is remembered, this warning is unnecessary.

Of course, if the spectator deliberately looks for the background, its varying uses will readily be seen, but if it is at all satisfactory it will be so entirely subsidiary that it might be included in fifty portraits without the

fact striking the beholder. The background must on account be selected for what may be considered its beauty, but solely as a ready means of isolating strengthening the portrait, though certainly a certain class of customer will be pleased with a background, however inappropriate, so long as it is ornate.

Small head grounds are amongst the most useful, are the easiest to obtain good, since they pack into small a space, and are easily handled. A number should be kept, since a very indefinite ground is usually considered the more artistic. They can frequently be turned upside down with advantage. One also obtains in this manner the choice of the light or dark portions of ground on the shadow side of sitter. A means of slightly raising or lowering the ground is advisable; a reliable method is that described in the JOURNAL for November 1905.

Cloud grounds of varying depths, if of not too great contrast, are extremely handy. A suggestion of foliage can be introduced occasionally with effect. Plain ungraded grounds are not entirely satisfactory in middle tones of grey, usually being too much of the same tones as the flesh, or giving undesirable relief to portions of the clothing. The plain white ground used with light dresses is useful, and it will be found that all tones, from a medium grey to white, are easily obtained according to the position of the ground with regard to the light.

A soft lighting is advisable in the majority of cases with a light ground, yet we have made striking effects with a strong lighting against a grey ground with a portion of dead black introduced in some form or another. A used a black straight band about three inches wide.

A deep black ground is intensely useful for men, light with a concentrated beam; its use has, in fact, almost amounted to a convention. Very brilliant effects are made by contrasting light clothing with it. Backed plates should always be used in conjunction with the dead black ground. It must be remembered when using the favourite dark grounds of the day that a cloth of agreeable depth when used for an adult with full exposure, is frequently objectionably sombre if the exposure has to be contracted as is the case when taking children. For full-length three-quarter figure, quite plain ungraded grounds are apt to give the figure an inlaid appearance, unless, indeed, the dead black ground is used. With this latter, however, a certain lack of atmosphere is often apparent. This is overcome if the background stretcher is slightly elaborated by having hinged side wings made of opaque black material, to open out at right angles to the ground; an opaque top should also be provided. It can easily be arranged to fold flat with stretcher, so that when not in use no more space than usual is occupied. When the sitter is placed on an imaginary line drawn from the extremities of the open wings, the lighting will not be affected in any way, whilst the ground will be of purest black, into which the shadows will sink with roundness and softness quite foreign to the harshness associated with the usual black background.

Though grounds have of recent times, and owing to the example of the finest American painters, improved wonderfully, at the same time there are still too many shocking untrue and inappropriate, and full of unnecessary dead and worse highlights. Interiors are not yet satisfactory some of them outraging common sense, truth, and taste. These scenic grounds are frequently provided with false grounds, which certainly, in the majority of cases, improve them; they are, however, rather in the way. If the cloth are on the usual 8 ft. by 8 ft. stretcher, we sew two loops of tape on to the extreme corners of the foreground,

provide two hooks on which to hang them, screwed into the stretcher frame at the requisite height from the floor. In default of really good artificial interiors, we provide a real interior, which is very satisfactory. The end wall of the studio—of course, if both ends are available they can be treated differently—is papered with a very dark self-colour paper, of a tone to match the rest of the decorations. A picture-moulding frieze and skirting board are provided. They form a very large background, suitable for large groups or single figures. A picture of very low tones, framed in black, is often used in conjunction with this wall, and perhaps suggests more insistently than anything else the atmosphere of perfectly natural surroundings. It is, moreover, so easily moved, raised or

lowered, that it becomes a most valuable aid to the composition, often, indeed, pulling a picture together or supplying necessary balance. One or two pieces of dark furniture add to the homeliness. They may be placed against the wall, and it is by no means necessary that they be in focus. After using a fine natural ground like this, a ground suitable as an interior for the highest or the lowest class, one never wonders at the pervading artificiality of professional work, but rather that the baronial hall, interior of cathedral, or pantomime palace type of background have existed so long.

We hope in a later article to deal with accessories, including much that may reasonably come under the heading of backgrounds.

## THE OZOBROME PROCESS.

The method of "chemical printing" invented by Mr. Thos. Manly, of the Ozotype Co., has been before the photographic world only three months, and yet, so far as we can judge has not yet aroused the interest which would have been anticipated from its remarkable character. It would seem that the process is such a complete revolution in methods of photographic printing that experienced printers are inclined to dismiss it without investigation of its powers by a series of practical tests. Ozobrome, however, as we were the first to assert, is no freak process or *tour de force*, but a method—of extraordinary simplicity—possessing facilities which must surely prove tremendous advantages in the eyes of both professionals and amateurs.

In the first place, ozobrome yields a carbon (pigment) image indistinguishable from a carbon made in the ordinary way.

This carbon print is made directly from a bromide print or enlargement, and it is unreversed.

The printing (in the dark) of the carbon from the bromide is done in about the time required for daylight exposure.

The bromide, after use, may be restored to its original condition. The whole series of operations is performed in broad daylight, or by any artificial light that may be preferred, and may be mounted and finished.

To the amateur worker who has not the opportunity of daylight for a large proportion of his work these facilities require no comment or emphasis. The professional photographer or trade enlarger can hardly help regarding the process with special

interest from the point of view of lessening the cost of reproducing carbon enlargements. Hitherto an enlarged negative has been indispensable, and in contrast with ozobrome the cost of the materials may be compared thus:—

15 x 12 ENLARGEMENT VIA ENLARGED NEGATIVE.	
	s. d.
Contact Transparency, say .....	0 2½
15 x 12 Negative Plate .....	1 6
	1 8½

15 x 12 ENLARGEMENT VIA BROMIDE.	
15 x 12 Bromide .....	0 6½

The cost of "printing" ozobromes from the bromide should be less for labour than in making carbons by the ordinary method, and would compensate for the slightly increased cost of the ozobrome tissues (pigment plasters) compared with ordinary carbon tissue.

The figures given above leave out any value of the bromide print, although, of course, a considerable sum might be obtained for it either in its raw state or worked up. It is to be expected that one bromide enlargement, in conjunction with one or more carbons of the same size, will become a stock line among photographers; but in any case it is to be hoped that the profession will make the lessened cost of production the opportunity of extracting a larger profit from such extremely "cut" specialties as carbon enlargements.

### THE REV. H. W. DICK ON OZOBROME AT THE NORTH MIDDLESEX.

On Wednesday evening last, September 26, the fixture at the North Middlesex Photographic Society was the Ozobrome Process, demonstrated by the Rev. Henry W. Dick, of Manchester. Mr. Dick, who has several times lectured before the Society, was met by a large audience, who fully appreciated the opportunity of witnessing the demonstration of Mr. Manly's fascinating process. Many other photographers would doubtless have been glad to have attended had the occasion been announced. The demonstration was, however, arranged at short notice, Mr. Dick kindly consenting to devote an evening to the subject in his passage through London for a brief holiday in Normandy.

He explained that the whole of the preparations for the demonstration had been made for him by others, and that therefore the success (or failure) of the proceedings was not to be credited to himself. The demonstration, however, was completely successful.

#### The Preparation of the Bromide.

The lecturer explained that the basis of the process was the contact of a bromide print with a piece of carbon tissue or

pigment plaster, as Mr. Manly called it, this contact producing the effect of light, and giving rise to a print which was to all intents and purposes a carbon. The bromide was bleached during the course of the process, but it could be used again and again if desired, or it might be made the basis of the carbon print, in which case certain advantages were obtained. In both cases the bromides should be good prints, fully washed to free them from hypo, the presence of which would unfit them for the process. The reason of this was that the solution with which the carbon tissue (pigment plaster) was impregnated contained ferricyanide of potassium, which, with any hypo in the print, would form Farmer's reducer, and so destroy the silver image of the bromide in places. The gelatine film of the bromide should also be hard, in order that it might not soften under the action of the hot water used for development. The prints could be treated with 10 per cent. solution of formalin, but it was not absolutely necessary to use this bath, though probably advisable to do so, unless the prints were to be dried before being placed in contact with the treated tissue (pigment plaster).

### Transferring the Bromide Image.

The bath in which the tissue or plaster was immersed prior to contact was called by Mr. Manly the "pigmenting solution." It consisted of potassium bichromate, potassium ferricyanide, alum, and citric acid. The solution was prepared and placed on the market by the Ozotype Co., though the lecturer believed that in the event of the secret of its preparation being lost he could re-supply it.

The solution as purchased was mixed with four or less times its bulk in water. The stronger the bath, the more quickly the transfer of the bromide image to the tissue would take place. However, an average formula would be as follows:—

Stock solution .....	2 ozs.
Water .....	8 ozs.

The tissue was placed in this solution, and at once swabbed all over on the gelatine side in order to remove air-bells and obtain a complete action of the solution. A minute or two was sufficient for the process, the only action of which is to impregnate the tissue with the solution. The bromide print was soaked in clean water until flaccid, and the treated tissue then removed direct from the pigmenting solution, and brought at once face down upon the picture side of the bromide print lying face up in the dish. The bringing into contact of the two prints must be done smartly, as the action of the solution adhering to the bromide commences at once. The pair is removed (in contact) from the water and immediately laid on a piece of glass, the bromide underneath. A few strokes of a squeegee are quickly applied to remove excess of the solution, and the double paper laid under slight pressure—e.g., a sheet of plate-glass about  $\frac{1}{4}$  in. thick, and somewhat larger than the print—for about twenty-five minutes or half an hour.

The pressure on the prints should be even; if it is greater at one point than another there is likely to be a line showing in the final ozobrome print. But a pile of prints of the same size may be laid together under pressure without any evil results.

The contact between the prints and the tissue is only of service whilst the two are wet. If the time is so long that the tissue or the bromide print dries, the action comes to a stop. Mr. Dick could not say whether the action would take place more quickly if the print and tissue were laid under pressure together in a warm, moist place, but he was inclined to think that there was likely to be little advantage in this direction, as the tissue would adhere permanently to the bromide print on moderate elevation of the temperature, and therefore the preferable form of the process in which the final ozobrome is obtained without the presence of the underlying bromide image could not be carried out.

Clean water must be used for each bromide print—that is to say, the water must not be contaminated with the drainings from the bichromated tissue, or the print will commence to bleach before it is in proper contact.

In regard to the time during which a print should remain in contact, the lecturer said that it was difficult to over-print, but the temptation to cut down the time of contact should be resisted. In making a number of prints, no time was wasted, and twenty-five minutes could be given to each print.

### Ozobrome on Bromide Print.

This first process was preferred by Mr. Dick on the ground that when certain modifications—not suggested or authorised by Mr. Manly—were made, the richness of the final print was greater than by the other process, and afforded facilities for remedying defects in negatives which were very valuable. Nevertheless, the second process, in which the pigment print is obtained, supported on single transfer paper, the bromides being liberated for repeated use, was the one which the lecturer advocated for regular work. The method of employing process No. 1

is as follows:—The bromide prints and tissue (pigment print) after twenty-five minutes' contact, are placed together in warm water, about 100 deg. Fahr., or, say, about as hot as the hand will bear. The paper support of the pigment film becomes loose from the solution, in the hot water, of the gelatine film, and can be stripped off, leaving the pigment on the surface of the bromide print. Development is done in the usual carbon manner by laying hot water over the surface of the print, and removing to a dish of cold water when finished. The print now consists of a complete pigment print, or a bleached or partially bleached bromide underneath. This can be employed in several ways:—

1. It may be removed altogether by the Farmer reducer.
2. It may be redeveloped with any developer.
3. It may be darkened with the ordinary soda sulphide solution used in the sulphide toning process.

The first of these procedures will be adopted if the print is to be used for nothing to be desired as regards vigour. If, however, it is to be used for strength, the application of either solution—developer or sulphide—will improve it.

In either case, it is a curious thing that more detail is visible in the ozobrome print than is visible in the original bromide print. In fact, according to Mr. Dick, this is the case even if the bromide image is altogether removed. It is suggested that the invisible constituent of the bromide comes into play in the ozobrome process. It is sometimes found that in ozobromes worked according to this first method, the resulting ozobrome may be flat, apparently due to some scattering effect of the lights in the subject. The addition of a little alkali (ammonia) to the pigmenting solution will remedy this, and is a great advantage in preparing ozobromes from flat prints. The quantity of ammonia may be about 10 minims of 10 per cent. solution of ammonia to about 8 oz. of pigmenting solution. Addition of potassium citrate would give the same result, the lecturer stated, but he was unable to say whether its action was due to the alkalinity of the compound, or whether a neutral citrate would give the same results as ammonia.

In the case of subjects with too much contrast (in the bromide print) a little acid added to the pigmenting solution will remedy matters.

### Pure Pigment Prints by the Ozobrome Process.

The second method of ozobrome was described as that which would be adopted for regular work, as it was independent of the bromide image underneath. It was as easy to work as the first. The first part of the procedure is the same as in the first method, both methods, the print and treated tissue being placed in contact, while wet, for about twenty-five minutes. Instead of developing at once in hot water the tissue and bromide print are laid in cold water and the bromide print pulled off the two being under the water while this operation is being performed. A piece of single transfer paper, which has been soaked in water for a few minutes, is then brought face down on the exposed surface of the tissue and the two removed together from the water. They are squeegeed in contact and laid under a weight, such as a piece of plate-glass, for a quarter of an hour. The pair are then placed in hot water and developed in the usual way, already described for the first process, being finally soaked in cold water, and given a brief bath of alum and a final wash in water.

Mr. Dick showed a number of prints made by both variations of the process, and stated that the three prints by himself in the Royal Photographic Society's Exhibition were ozobromes.

The very greatest interest was manifested by those present in the process, which, it was acknowledged, fulfilled all the claims which were made for it, remarkable and almost incredible some of those claims were. The advantage of the chemical printing of the copies without light and of the non-reversal of

prints was commented upon, and Mr. J. C. S. Mummery, in proposing a vote of thanks to Mr. Dick, expressed the hope that

### OFFICIAL INSTRUCTION FOR OZOBROME.

Since the publication of the first directions for the working of Mr. Manly's process, the following additional notes have been issued by the Ozotype Company, from whom, we have no doubt, they will be obtainable. They will supplement the directions appended to an article by Mr. Foxlee, which appeared in our issue of June 29, contribution which was the first to give the photographic world information of this remarkable process. We may be pardoned for alluding to this point, but our attention has been drawn by several readers to the statements made by two of our contemporaries, each of whom claims to have been the first in communicating details of ozobrome. Both were several weeks after the BRITISH JOURNAL OF PHOTOGRAPHY.

It is possible that 1 part of the concentrated pigmenting solution to 5 parts of water may not be strong enough to completely bleach deeply-printed enlargement. Perhaps 1 part of concentrated solution to 4 parts of water might be considered as the average strength of the pigmenting bath. This strength will keep better than 1 part to 5 parts of water.

#### Safe Edging.

In Method No. 1, the bromide picture should be printed with a white margin of about half inch all round to serve the purpose of a safe edge, so as to prevent the edges of the picture from frilling during development.

In contact printing the margin formed by the rebate of the printing frame is generally sufficient, but in making enlargements the margin of the bromide paper should be protected. This may be easily effected in the following manner:—

Take a sheet of cardboard the size of the bromide paper (the straw-

board packed with the sensitive paper will answer admirably), paste or glue strips of thin cardboard or stout paper of any colour along each edge of the card, allowing about half an inch of the paper to project from the edge. When dry, turn the half-inch edge over the card, so as to form a kind of sheath, such as is used for carrying plates in some magazine hand cameras, but, of course, with four edges protected. You have now a very handy contrivance, which will be always serviceable. When about to expose, slide the sensitive paper into the sheath by unbending one side and replacing it. Adjust on the easel by pinning through the card.

#### Modifying the Picture.

In Method I., the bleached image beneath the carbon picture may be redeveloped partially or entirely, and this may be made use of in various ways. For instance, a weak bromide may be converted into a strong print by re-blackening the underneath image, and many beautiful effects may be secured by causing the redeveloped silver to modify the tone of the semi-transparent carbon picture.

If a weak developer be applied with a brush, local intensification may be effected, and a sky which is hardly strong enough for the rest of the picture may be made heavier in this way.

The underlying image may also be toned by the various bromide toning solutions.

Of course, the developing or toning solutions must be removed by washing for about fifteen minutes.

The redeveloped silver image, being protected from the atmosphere by a layer of hardened gelatine, is naturally much more permanent than an ordinary bromide print.

## BARON VON HÜBL ON THE "UTO" BLEACH-OUT PROCESS OF COLOUR PHOTOGRAPHY.

In the current issue of the "Wiener Mitteilungen" Baron von Hübl describes the results of his experience with the new commercial "Uto" bleach-out paper of Dr. J. H. Smith and Co., of Zürich, now commercially obtainable.

Although the principle of the bleaching-out process has been known for some years, successful results have hitherto been hardly possible, or there are many difficulties in the way of making a paper that will print well and with certainty. The well-known firm of J. H. Smith and Co., of Zürich, have, however, overcome, to a great extent, these difficulties, and placed on the market the so-called "Uto" paper, by means of which it is possible to learn the peculiarities of this interesting process.

The paper has a black film, and gives, on exposure under a coloured transparency, a print in the same colours. The process proves the possibility of obtaining any desired number of prints from an original, e.g., a transparent three-colour picture, and it may play the same rôle in three-colour photography as the ordinary printing processes of black and white photography.

The black film consists of a red, a blue, and a yellow dye, and contains—besides certain additions—sensitisers, which make the dyes fugitive to light; when exposed to light they soon bleach completely.

#### Principle of the Bleach-Out Process.

The formation of the colours during exposure can be easily grasped, when one considers that a dye can only be bleached by those light rays which it absorbs, whilst the rays, which it reflects, cannot affect it. In red light, therefore, the film of dyes must become red, because the red dye therein is not changed by these rays, for it reflects them, whilst the blue and yellow dyes are bleached. The same considerations will show that the black mixture of dyes will become blue in blue light, in yellow it will become yellow, and that in green light the red dye only will bleach, and the film will become green, and so on. In white light all three dyes will bleach, and therefore the mixture will become white.

The colour of the black film, therefore, always adapts itself to the colour of the incident light, and when a paper coated with such a mixture is exposed under a coloured transparent original, a print in the same colour must be formed.

Colours true to the original can, however, only be given if the three dyes are of the same light sensitiveness—that is, if the black film assumes no colour in white light, but gradually passes through neutral grey to white.

This condition is, however, very difficult to fulfil, as the dyes behave very differently towards the present known sensitisers. The best results are obtained in the meantime with the so-called "film papers," in which the dyes are not mixed, but are coated one on top of the other, in gelatine or collodion, with a suitable sensitiser. By this means also any simultaneous chemical reaction of the dyes is avoided.

#### The Composition of the Sensitive Film.

Thus the "Uto" paper contains two films of dyes, a red erythrosine gelatine film, and on top of that a green collodion film, which owes its colour to a blue and a yellow dye. The green film contains as sensitiser anethol, a substance which was recommended by Karl Worel, and, with the new dyes used, is extraordinarily active. The red gelatine film, on the other hand, appears to possess no sensitiser, but must be made sensitive by bathing in solution of hydrogen peroxide. The use of this for sensitising was first suggested by Dr. Neuhaus, and it is especially useful for dyes of the cosine group.

J. Szczepanik worked in a somewhat similar manner, only he used a colourless gelatine film on top of the blue-yellow collodion film, and bathed the green paper before use in a solution of erythrosine, containing hydrogen peroxide.

There are considerable difficulties in coating the dye films of the bleaching-out paper, as the dyes have always a tendency to penetrate the fibre of the paper, and one film has a tendency to diffuse into the other. In "Uto" paper these difficulties are overcome, as a specially prepared paper is used, into which the red dyed gelatine does not

penetrate, and which, on the other hand, is so permeable to the hydrogen peroxide solution that the erythrosine film is easily sensitised from the back.

### Working Conditions.

"Uto" paper shows, from its composition, the following peculiarities, which must always be borne in mind when using it:—

1. The unsensitised paper does not become white, even with very long exposure, but assumes a crimson red colour, for only the green film bleaches.

2. After sensitising with the peroxide, the dyes bleach fairly evenly, and, under favourable conditions, prints true to the original, with pure grey tones, can be obtained.

3. The activity of the hydrogen peroxide soon decreases, and completely ceases when the paper becomes dry. The prints must thus be finished before the paper becomes dry, therefore one can only print in direct sunlight.

In the shade only red prints are obtained, and also a piece of paper exposed by itself will not turn white, but remains red, as it dries before the complete bleaching of the erythrosine film. The paper only remains damp sufficiently long to completely bleach when in intimate contact with the original.

If the paper, therefore, is not used soon after sensitising, or the light decreases during the exposure, reddish tints are produced. In such case supplementary sensitising may be resorted to. The printing frame should be opened and the back of the paper covered with a sheet of blotting-paper, soaked in hydrogen peroxide, and half dried. As the damp "Uto" paper adheres tolerably firmly to the original, one need not fear any movement.

On the other hand, a freshly sensitised paper may give greenish tones in very strong light, for the red film bleaches too quickly. In this case it is advisable to cover the printing frame with a sheet of glass, coated with erythrosine collodion.

If attention is paid to these points perfect colour prints can be

obtained on the paper. The chief fault lies in the necessity of the unreliable peroxide sensitiser, which, as already mentioned, is essential, from the choice of erythrosine as the red dye. For this reason J. H. Smith and Co. are now endeavouring to find a substitute for erythrosine, a crimson dye, which will also react with the yellow and blue dyes with a dry sensitiser, and we must wait to see that these experiments will be brought to a successful conclusion.

The necessary time of printing with the present commercial process depends essentially on the intensity of the dye films. If the paper is thinly coated an exposure of from 20 to 30 minutes is enough in sunshine. In this case the paper shows only a dark grey colour, which, however, in the finished prints, is almost as good as black. If, on the other hand, the dyes are thickly coated, the paper appears before exposure, black, and then an exposure of an hour or more is requisite.

The fixation of the coloured prints presents no difficulties. The hydrogen peroxide is destroyed by complete drying of the print, and in order to remove the anethol several hours' soaking in benzene is required. As this sensitiser in "Uto" paper lies in the film, it can be easily removed.

The pictures obtained by means of the bleaching-out process actually deserve the designation of "colour photographs," for the dyes give the colours, and these are directly produced by the action of light.

The process will become especially valuable, when we shall succeed in obtaining the coloured transparent originals in a simple and certain manner. The present process of obtaining such pictures by the superposition of three monochrome constituent prints is a very practical work, far too troublesome and difficult, but it is not impossible that this goal may be obtained by a trichromatic or screen process in a very short time. Every advance, therefore, even now in the bleaching-out process will be welcomed in a friendly manner, and such, without doubt, "Uto" paper is.

A. VON HÜ

## THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

### THE PROFESSIONAL SECTION.—(SOUTH ROOM.)

"ROYALISTS" usually claim for the Selecting Committee in the Pictorial Section at the New Gallery a considerable catholicity, and maintain that the pictorial work hung in the West Room is of all schools. In considering the professional work in the South Room (which will, no doubt, prove of special interest to those who are able to see it) we shall endeavour to show the same catholic spirit, and we may at once point out that both the purse and degree of artistic perception of the clientele must needs be reckoned with by the commercial photographer, who is, after all, in business to make money, and not to air any high-falutin' ideas on Art.

At the same time, we hope to point out how, in certain cases, work may be considerably improved from an artistic point of view, thus attracting more attention from the cultured and refined without in any way alienating those who demand what they may term plain, straightforward photography. Some of the portraits shown display a tendency towards eccentricity pure and simple, which, though it may occasionally be thought valuable (as we have been shown this autumn in another place), is nevertheless in danger of being overdone.

Before proceeding to a more detailed criticism of the groups of exhibits, we may call attention to the somewhat ineffective, and, therefore, defective arrangement of the the majority of the displays. Taken as a class, photographers are notoriously deficient in their ability to "stage manage" the studio and shop. The groups of work in this room exhibit the same defects as the arrangements in most show cases or shop windows. Mr. William Crooke, of Edinburgh, has made a most effective display with half a dozen prints on a

whole wall; but some of the other groupings would be better if half the work had been exhibited. Lack of scheme is another point, to which attention might well be given, both in a wall display, such as these, or in the arranging of work in the window. All kinds of portraits, often in various processes, together, and the general effect is less harmonious than it would be if a special show were made of children's portraits, theatrical views, and so on. If it were felt that a professional display should be comprehensive, then the work might be so disposed on the wall as to consist of a group of groups.

Miss Stephanie Maud, of 25, Harrington Road, S.W., shows an ambitious work, a good deal of which lacks finish. It has been said that finish is the one great difference between the work of a trained and the untrained. Artistic perception, which may be said to be the mark of a photographer, will frequently enable the happiest effect of lighting or arrangement and the most charming of expressions to be secured on the plate, but the manipulative skill needed to prepare a print and adequately mount the print is only to be obtained by careful training and a good deal of practice. Several of the portraits are weak bromide prints or enlargements, in one case at least, marred by a yellow stain on the edge of the print. A piece of *passe partout* mounting is crude, lacking precision and neatness. However good the wine, bush is necessary. There are also on the wall two portraits which show incongruity, the most noticeable being that of a lady in evening dress, sitting on the floor on a large white cloth, and leaning against a painted exterior background. Such mistakes here might easily have been avoided by a few moments' reflection before arranging the sitter.

The work of Histed, of 42, Baker Street, W., is curiously uneven. The effect of light and shade in most of the specimens borders on the eccentric, and is pursued without the least regard for truth to tone values. Concentration of light, and, consequently of interest, on the face is all very well, if properly done, but when this concentration exists on only about one-third of a face, truthfulness goes by the board. Forcible lighting, with a preponderance of shadow, is a characteristic of Rembrandt's work, but the shadows are luminous, or, at all events, transparent. In many of these prints the shadows are under-exposed, or if the negative has any detail in the shadows it is so strong and so deeply printed that the shadow gradation is lost in the print. A portrait of a child, masked with an oval mask, is noticeable for excessively heavy flesh tones, absolutely out of place in such a subject, which should in general be treated lightly and daintily. Nothing is really gained by the effects obtained by this falsifying of tones in the flesh or draperies. One of the best, and, at the same time, the most effective of the portraits is a cabinet-size print of an elderly gentleman, which is mounted on a dark-grey mount. Here the modelling of the features and the general roundness of the head is excellent, and one wishes to see more of such strong direct straightforward work.

James Clark, of Hanger Lane, Ealing, W., has a display which includes some sound portraiture, one or two of the enlarged portraits being very good commercial work. The coloured enlargement is effective, the colour being free from any of that crudity which too often occurs in work of this class. Of the smaller prints, there are too many, and a judicious weeding out would have improved the general effect of the display. Most of this small work lacks distinction. The technical quality of negative and print may be all right, but the public rightly place other qualities before mere technique, important as that is. Strength, character, and individuality seem to be lacking in many of the cabinet prints. Were they lacking in all of the sitters, or has the operator failed to educe them before making his exposures? Mr. Clark's fancy picture is, perhaps, better than the one he exhibited on the same wall a year ago, but we frankly admit we do not care for it, and we do not think it is the kind of photograph likely to enhance a portraitist's reputation. The make-up is obvious. The monk is apparently consuming macaroni from a plate, and is using his fingers for the work. The whole thing lacks refinement and dignity.

H. S. Mendelssohn, of 14, Pembridge Crescent, W., shows a group of his well-known photographs, some of which represent the high-water mark of commercial portraiture, while others are singularly below the artist's standard. It is worthy of note that all these prints are by the silver process, whether on albumen paper or on P.O.P. it is not quite easy to determine through the glazing of the frames, though we believe most of them are albumen. The colour of print has been characteristic of Mendelssohn's work for a great number of years, and is a rich warm purple brown, a colour easier to obtain on albumen than on P.O.P. The prints are numbered, so that it is easy to refer to any of them with certainty. No. 11, a portrait of William Carter, Esq., is excellent, quiet in treatment, soft in its gradations, and yet quite rich and strong enough for a man's portrait. In No. 8, Miss Leonora Jackson, there is noticeable a delicacy of gradation in the high lights, together with strength in the print and good shadow tones. No. 12, Michael Hambourg, Esq., is a fine lesson on the subordination of the tone of the hand, which is several tones lower than the face, and yet does not look "dirty" or false in tone. We do not, however, like the strong light on the book right on the extreme edge of the print, and it is so strong that it catches the eye before anything else. The nine portraits of rather more than cabinet size in a long frame are quite in the style one expects from the studio in Pembridge Crescent. The pose in No. 5 is not so pleasing and reposeful as in many of the other portraits. The knee appears to be too high, nearly on a level with the waist, and the light on it produces an unpleasant effect.

In the display of work by Wilfrid Jenkins, 116, Cromwell Road, South Kensington, there is, we think, the most even quality of work in the room, if we except the prints by Mr. Crooke. The portrait of a lady wearing a hat, the only print on a brown mount, is excellent. The photographer has realised that one measures height

to the shoulders or eyes, and not to the top of the hat, and so has rightly "placed" the portrait on the plate, the space between the top of the hat and the edge of the print is slight. Neither a dwarfed, nor yet a very tall appearance of sitter is suggested. The lowering of tone of the lace fichu should also be noted as the right way of doing it, in contradistinction to the crude sunning down of other prints already alluded to. We are assuming that these effects are produced by sunning down, as, of course, they may be. Whatever the means employed, whether this, or local reduction, or frictional reduction on the film of the negative, the final result is practically the same. In this portrait by Mr. Jenkins, the lowering of tone of the lace is so delicate that there is no suggestion of murkiness, and yet the desired effect of concentration of interest on the face is satisfactorily obtained. There are here several pleasing portraits of ladies with children, the arrangements being well thought out. Of the portraits of children alone several are capital, both in the seizing of expression and the general rendering of flesh tones. We think, perhaps, in one or two cases, the effect would have been better had the head not been quite so large.

The work of the Art Photographic Company of Stoke Newington and Muswell Hill is evidently intended for the middle-class portion of the community. A picture of a child pouring out tea into tiny cups, while a dog watches from the opposite side of the tray, is the kind of thing, while it is not great from an artistic point of view, appeals to the photograph buying public, and attracts a good deal of attention and comment when placed in a shop window. It is, happily, free from any suspicion of vulgarity. A fairly good example of Rembrandt lighting may be seen. An outdoor portrait of a lady standing partly under a trellis porch shows far too heavy shadows for an open-air or semi-open-air picture. The shadows, in fact, are too solid for any rendering of flesh, unless possibly when lighted by an artificial illuminant of extreme brilliance and concentration.

Mr. Eric Worsley Benison, of Egham, Surrey, has a few frames showing clean, straightforward work. We think the expression in the portraits is well secured, and the pictures convey the impression that they are good likenesses, though one does not know the originals. They appear a trifle hard, however, on the wall, but Mr. Benison, no doubt, knows that a picture which looks well on the wall of an ordinary room will frequently appear weak when hung at an exhibition such as this. These enlargements are not weak in their shadows, but the high lights and half-tones are rather too light for richness of effect.

Much of the work sent by Crooke, of Edinburgh, is so fine that to attempt criticism would be to lay ourselves open to the charge of finding fault merely for fault-finding's sake. The student of portraiture should note the masterly strength and dignity of the figure in No. 13, and also in the portrait of the late Sir Henry Irving. There is a reserve in the treatment of both these pictures, they are full of detail—sufficient detail, that is, for prints of such size—yet nothing whatever distracts the attention from the fine characterisation of figure and face. In No. 7 the fine treatment of hands should be observed; there is no distraction from the face, and no clashing of lights. The arrangement of the hands and other parts of the figure, as well as portions of furniture, give added dignity to the portrait, and are admittedly in unison with a face so grave, distinguished, and, withal, kindly. No. 6, a group of Mrs. Robert Cowan and children we do not like so well as some other similar portraits which Mr. Crooke has produced. The darkening of the hair against the background appears to be too uniform, the hair of the three sitters being equally dark. The portrait group of the Master and Assistants of the Merchant Company of Edinburgh is a fine achievement. Likeness is nowhere sacrificed to pictorial arrangement, yet this is secured in no small degree. The very even lighting of the heads and figures will at once call forth the admiration of the practical photographer. It is a great pity that such groups are not far more frequently taken of our great directorates, city companies, and other public or semi-public bodies. They would be extremely interesting and valuable in a hundred years' time. The visitor will notice that the numbering attached to the frames is not in accordance with the numbering in the catalogues, but this rarely prevents identification of the pictures, and they may all be enjoyed for their own qualities, and quite apart from the personality of the distinguished sitters.

## THE SCIENTIFIC AND TECHNICAL EXHIBITS—INVITATION SECTION.

The first exhibits we come to in this section are those of Mr. Douglas English, who shows some remarkably fine photographs of the Plume Moth (No. 414), and some interesting examples of mimicry in insects (No. 416), which illustrates the strikingly successful attempts of a spider to imitate a flower-bud, and is perhaps most attractive. Astronomical photographs are numerous, and while Nos. 419 and 423, from the Royal Observatory, illustrating nebulae and star clusters, are very fine specimens, Nos. 429 and 430, from the Solar Physics Observatory, are especially interesting, as they show the great success attained at South Kensington in photographing the mysterious solar prominences. No. 429 shows a most exceptional number of prominences, and No. 430 one of extraordinary size, its height being about 139,000 miles. Sir W. J. S. Lockyer shows some good specimens of cloud photography, while Captain D. Wilson Barker's collection of cloud types is also worth study.

A most interesting exhibit is that of Dr. R. A. Reiss, showing the application of photography in the investigation of crimes and detection of criminals. Nos. 444-447 show how readily an erasure and forged surcharge can be detected in a photographic enlargement, and No. 448 illustrates how photography can reveal the fact that an envelope has been opened and refastened. In No. 449 samples of finger prints are given, and in No. 450 we are shown photographs of footprints in earth, and of shoe-nail marks on a wood floor. Also one of a blood-stained handkerchief, revealing stains that have been washed out and rendered invisible to the eye. No. 452 is of especial interest, as it shows an ingenious ring-shaped cutting tool for making holes in safe doors. This tool is armed with diamond or carborundum splinters, and acts in much the same way as the diamond drill used for making boreholes.

Nos. 454-483 form a long series of photographs by Mr. K. J. Tarrant, of high tension electrical discharges, and the interest of these is

not solely scientific, though their scientific value is great. Close inspection reveals some most beautiful formations in these photographs, and special attention should be given to the wonderful ture of the plume-like formations in No. 456. The example reversal shown by M. P. Preobrajinski are worth study (Nos. 490-494) but the voluminous notes which accompany them take some time to read.

Perhaps the exhibit of greatest scientific interest (from the photographic point of view) is Mr. C. E. Kenneth Mees' gradation photometer. This is a cleverly designed instrument that undoubtedly fills a "long felt want," as it enables the user to determine the speed of a plate by direct observation and without any wearisome measurements and plotting. To effect this a developed series of test gradations is observed (five steps at a time), and compared and matched with a standard series of gradations, the steepness of which is adjustable, while its densities when plotted form a straight line. When a match is secured between five trial densities and five on the standard scale, all necessary data are, of course, secured. Other interesting but not such novel instruments are shown by Mr. Adam Hilg. These include a comparison photometer designed at the suggestion of Mr. F. F. Renwick, and a modified spectrophotometer.

A series of Lippmann photographs of the spectrum is contributed by Mr. Edgar Senior. These are not in the gallery, but are in the charge of the Secretary. They are interesting, but it is not easy to see them perfectly, as properly adjusted viewing apparatus is not available at present.

The lantern slides in this section are all three-colour, and they are supplemented by stereo, half-plate and quarter-plate transparencies. They are all natural history subjects, and on the screen would doubtless be most interesting, though as shown they can hardly be studied to advantage, and cannot be easily identified, most of the labels being invisible.

## THE COMPETITIVE TECHNICAL SECTION.

The only medal in the exhibition goes to Mr. C. Welborne Piper for a "model of light pencils showing various effects of aberration." The award has been criticised as not photography at all, but such criticism is misdirected, in our opinion, inasmuch as Mr. Piper's work is in line with the avowed aims of the society in advancing the progress of photography. That the exhibit is a highly educational one we cannot deny, and we hope to see more of its kind used in the teaching of photographic optics, though we fear there are few prepared for such feats of patience as Mr. Piper has performed. The models show:

Central aberration and eccentric coma. Actual model from lens.

Oblique coma. Actual model from lens.

Oblique and eccentric coma. Actual model from lens.

Oblique coma. Details of pencil in zones and at foci. The complete foci are shown in blue and yellow, the blue portions being filled by other zones not shown.

Pure and mixed astigmatism. Hypothetical model.

Pure astigmatism. Details of pencil and foci. Hypothetical model.

Studies of birds and animals form a very striking feature of this section, and their number suggests that before long such subjects will require a section to themselves. All the work of this nature shown may be styled good, and some of it shows remarkably perfect technique, while in a few cases the results are distinctly of a decorative and even of a pictorial nature. Striking examples are No. 284, The Great crested Grebe, by Mr. William Bickerton, who is not only a fine study of a grebe sitting on its nest, but is also a fairly good decorative composition. Mrs. L. Birt-Baynes, in her wolf and deer studies (Nos. 324-328), has gone a step further and has produced some charming little pictures in addition to securing some very perfect and characteristic portraits of her shy sitters. Nos. 324 and 325 seem to suggest the cowardly character of the wolf to perfection. The first one is particularly worth notice, as it represents the wolf slinking round a hillock with every apparent intention of doing such mischief as he safely may, but fully prepared to take to his heels on the least sign of danger to his precious self.

Among the bird studies the most successful appear to us to be those of Mr. William Farren, though Dr. Heatherly, and Messrs.

Frank J. Martin and Oliver S. Pike run him very close. Mr. Pike should have much cause for congratulation in being so highly successful with such rare birds as kites and eagles.

There are numerous photo-micrographs, Mr. Arthur E. Smith showing a good example in his foot of spider (No. 340), and Mr. J. Inderwick Pigg scoring a success in Nos. 342-3 with his heads of tapeworms. No. 348, by Dr. Rodman, shows the pollen of hollyhock and is a very curious and interesting example.

In the photography of insects Messrs. Forrester and Hugh Main are highly successful. The former's dragon fly (No. 351) is excellent while Mr. Hugh Main's frame of diving insects shows fine technique and is of great scientific value. There are some good studies of fruit and flowers that seem somewhat out of place in the scientific section as they certainly would not disgrace the West Room. Messrs. Edward Seymour and Robert Burnie are specially good in the examples. No. 356 is a series of photographs by Mr. D. Finlayson showing the fertilisation of white clove, and No. 357 is another series by Mr. Alfred W. Dennis, illustrating the details of the wych elm. Both these frames are worth study, and are of considerable scientific value from the educational point of view. In 361 and 362, Mr. J. C. Burrow gives some good specimens of flashlight work in the depths of a coal mine, and then we come to a long series of studies of sand waves by Dr. Vaughan Cornish. These, perhaps, are not of much interest to the uninitiated, though we did observe some visitors studying them very closely under the impression that they represented glaciers, but, scientifically, their value is undoubted.

The architectural exhibits do not strike us as particularly successful. The subjects have for the most part been photographed hundreds of times before, and some of them are seldom absent from a photographic exhibition. A few are of the "pretty peep" order, and possibly would have been more in place downstairs, where much better specimens of architectural photography are to be seen. G. Suter shows some good Alpine views that again seem rather out of place in the scientific section. Nos. 389 and 391 are both good specimens, and we do not quite see why they should not be classed as pictures, even though they may not be in the conventionally pictorial style, that, for the time being, is in fashion. In the specimen

which represent the application of photography to copying pictures and prints, and in representing sculpture, the best sample appears to be Mr. Howard Eslers "Greek Mother" (No. 401). This is a photographically perfect representation of a fine Tinworth panel. The three-colour work in the gallery is to us decidedly unsatisfactory, the only specimen worth mention being No. 408, a portrait made by the St. James' Studio. The best colour work is to be

found in the lantern slide collection belonging to this section, which collection is in the north room downstairs. Dr. Hutchinson (one of last year's medalists) shows a fine series of anatomical and pathological slides in colour, while Mr. Oliver S. Pike contributes a series illustrating birds' nests. The few monochrome slides on view are not eclipsed by the colour slides, for some very fine specimens are contributed by Dr. Francis Ward and Mr. Ellis Kelsey.

## THE PHOTOGRAPHIC TRADE AT THE EXHIBITION.

The Fountain Court at the New Gallery has its fountain submerged by the stand of the Adhesive Dry Mounting Co., Ltd., which, upon its moist substratum, and in apparent ignorance of the irony of their position, exhibits the apparatus for, and process of, dry mounting, and the accessories which they can supply in the shape of mounts, bronzed border tints, albums, etc. The process is one "par excellence," which lends itself to demonstration, and the exhibition which the firm is able to give is among the most popular items at the Gallery. We have no doubt that anyone who arrives at the R.P.S. with a print and mount will find the Adhesive Dry Mounting Company ready and willing to fix the one to the other by their process.

The Platinotype Company occupy their accustomed place, and are equally fortunate in having a process which can be shown from first hand under the eyes of the visitor. This year the new "Japine" paper is strongly in evidence, and the results with it which are shown with other examples of the platinotype process should not be overlooked.

Messrs. Kodak, Limited, have a representative assortment of apparatus, including the now well-known "Graflex," a high-class reflex camera. They also show specimens of the new "Velvet" bromide and gaslight papers, and are prepared to discourse to the visitor on Kodak products in general.

There is no more effective display in the exhibition than that of Wellington and Ward, who, among some specimen negatives on "Speedy" plates and prints therefrom on their various papers, have the results of a new introduction of theirs, a gaslight transparency plate of which we shall say more when we have had the opportunity of testing it.

J. H. Dallmeyer, Limited, show the new shutter for studio cameras, the characteristic of which is its wafer-like thinness, and the fact that it is obtainable in any size up to a diameter of working aperture of five inches.

Messrs. Sanger-Shepherd and Company attract a continual audience by exhibits of colour-photography, they having arranged a small projection apparatus with which to exhibit enlargements of the Sanger-Shepherd transparencies. They also show the latest models of the three-exposure camera, and are making a strong feature of their recent advances in plates and filters whereby the average exposure for the three negatives out of doors is only about four seconds. This is the time required when using a repeating back, a form of three-colour exposing apparatus which has always been strongly recommended by the firm.

Messrs. Sichel and Company place the new mercury-vapour lamp, viewed in another column, in the front place. They also show a number of very effective results obtained on a two-colour carbon process from ordinary negatives. "Platinochrom" platinum paper and its results are also shown, in addition to a variety of mounts—the latter interested us especially, and though Messrs. Sichel cannot display them, every professional visiting the exhibition should ask to see them—and of studio cameras.

Messrs. C. P. Goerz make their usual striking show of enlargements on negatives taken with the Goerz lenses, notable among which is one of detail in the Albert Memorial, made in the first instance with a Goerz telephoto at a magnification of  $7\frac{1}{2}$  times, and subsequently enlarged to five diameters.

Messrs. W. Watson and Sons show their cameras and "Holostigm" lenses, and exhibit also the Boardman arc lamp and some beautiful examples of work in West-End studios done with it. The latter could be asked for and inspected by our professional readers.

Messrs. Burroughs, Wellcome and Company make a neat but effective show of "tabloid" chemicals and specimens of results of their work, particularly in the direction of lantern-slides.

A new model of the Blacknote, viz., one taking a picture,  $3\frac{1}{2} \times 2\frac{1}{2}$ .

is shown by Messrs. Sanders and Crowhurst, who exhibit also Messrs. Butcher's latest edition of the Welborne-Piper clock. This modified form of the instrument allows a shutter to be left open for exposure and the clock to be set to a certain time, on the attainment of which the shutter will be automatically closed.

The approach to the north room is occupied by Messrs. A. E. Staley and Company with a case containing a large selection of their apparatus, chiefly optical (lenses, microscopes, etc.), but a note should be made of the prints illustrating the performance of the firm's anastigmats.

In the north room itself, the first display to attract the eye is the collection of portraiture by Mr. F. C. Clarkson illustrating the Eidoscope lenses. Among the specimens are several showing the extremely sharp results which can be obtained with the lenses if desired, which are the more interesting since the chief purpose of the instruments, and one which they will be seen to carry out to very good effect, is the production of portraits with enough diffusion of definition to improve upon the biting sharpness of the ordinary objective.

The Ilford Company make a small display of great specific interest, viz., enlargements on their various brands of "Bromona" paper. These show the effects obtainable with and without toning, No. 1 being in particular a good example of the fresh airy effect obtainable on the bluish-grey paper. No. 5 shows the pleasing results in portraiture of a toned cream-crayon "Bromona." The selection is a strong one, and quite characteristic of the Ilford's Co.'s specialistic methods.

Next in order comes the most interesting exhibit of the Ozotype Company, which this year, of course, is all ozobrome. Readers of the article on another page had better study the examples shown side by side with the original bromide prints from which they were made.

Messrs. Morgan and Kidd make a handsome display with a series of fine portraits on the "Richmond" self-toning, a selection which suggests that they are seeking the favour of the professionals for their product. Certainly the fine, cool black tones obtained by their special process of platinum toning leave little to be desired. The two panels on either side of these latter show the effects obtained with plain fixing, and are very strong recommendations of the paper.

The exhibit of L. Thornton and Co. is catalogued as "a collection of prints on 'Mattos' paper, but it includes also one or two (which are worth searching out) on wood and canvas sensitised by the "Mattos" method.

The largest exhibit next to the Autotype Co.'s is that of the Leto Photographic Materials Co., Ltd., which occupies the whole of the end of the north room. It contains some strikingly handsome specimens of the Pluto-Leto "Platino" paper, of deep rich black tone and showing the excellent results of which this paper is capable in rendering the details and texture of white draperies. A number of examples of Leto gaslight paper toned to various colours is worth examining, and there are also numerous specimens of the Leto Platino papers, Seltone, and other well-known specialties of this firm.

The huge show of the Autotype Company is extremely successful, and fills the north wall in an imposing way. The first panel, of portraiture on the various carbon tissues and worked up in several ways, is the most interesting to photographers, and includes one or two remarkably good things in the way of coloured prints. Two specimens are shown of the Autotype three-colour printing on the "Trichrome" tissues.

The last exhibit to be mentioned is that of the Falla-Rey Company, of Tunbridge Wells, which shows a number of postcards and prints obtained on a paper which is said to require only a fixing of one minute's duration and a washing of five. We have no information of this material, and should await an opportunity to verify the claims made for it with some interest.

## "THE GLOBE" ON THE "ROYAL" AND "SALON."

In its issue of Wednesday, September 26, the "Globe" makes the following comments to which we refer under "Ex Cathedra":—

There are to be seen at the present moment two important exhibitions of photographs—that of the Royal Photographic Society at the New Gallery, and that of the Photographic Salon in the gallery of the Royal Society of Painters in Water-Colours. The object of these exhibitions is, it may be presumed, to show to the world the progress and development of the art of photography, and to prove that, as an art, it has a claim to the consideration of people of intelligence and taste. That photography properly used and understood deserves an honourable place among the arts is certainly not to be denied, but that either of these exhibitions proves what this place should be cannot by any means be admitted. Both shows, indeed, are painful advertisements of the incapacity of photographers as a class to understand the genius of the art which they misuse; both have an atmosphere of foolish insincerity which is particularly irritating, and show in the plainest way how little the people who use a camera appreciate artistic responsibilities. It is the degeneration of a most important craft that is illustrated in the two galleries, not its progress nor the development of its best characteristics.

The reasons for this degeneration are evident enough. Photography has fallen largely into the hands of a class of workers who possess at best nothing more than that little knowledge which is proverbially so dangerous. The so-called artistic photographers—with very few exceptions—have not learned the rudiments of pictorial art, and are imperfectly acquainted with the technicalities of photography; so they produce things which are marked by an all-round inefficiency that is very distressing. Through lack of the right kind of training, they have no capacity to realise the qualities of the medium they employ, and as a consequence they condemn photography to undignified imitation of other arts to which it is not in the smallest degree akin. The directions in which it can be used to produce results unattainable by any other pictorial process they deliberately ignore, and they waste their energies in torturing the photographic print into imperfect resemblance to the work of the water-colour painter, the etcher, the lithographer, or the draughtsman in black and white.

In both exhibitions examples of this misdirected effort predominate—examples of what may reasonably be called technical dishonesty. Neither show includes much that can be welcomed as the expression of a sincere desire to use photography for the right representation of nature; the great majority of the works brought together are deficient in all subtlety of tone relation, in all delicacy of atmospheric effect, in accuracy of definition, and charm of quality, and most of them have as well grave faults of selection and arrangement. The things that the camera can do to perfection are for the most part avoided, and those which advertise its deficiencies as an artistic instrument are attempted with ignorant perversity. If such collections as these sum up the best that modern photography can do there can be no doubt about the disastrous degeneration of the art.

For instance, in the exhibition of the Royal Photographic Society practically the whole of what is described as "professional" work

repels by its entire lack of originality and by its utterly uninteresting and commonplace aspect; and the section devoted to "pictorial" photography contains little that is æsthetically of any value. Examples as Mr. L. Fleckenstein's "The Pet Angora," Miss Willis's "The Snowstorm," and Mr. P. Pichier's "Arkadien" taken as types of the inartistic productions which have been produced by so large a proportion of the contributors. These things, host of others of the same order, make the show a painful disappointment to all serious believers in the future of photography because they mark a tendency which is apparently becoming more pronounced year by year, and more demoralising to the less intelligent students of the photographic craft.

However, there are some exceptions to the general run of work which are worthy of special attention, because they point in a direction in which sound achievement must be looked for in the future. Mr. E. B. Cook's "Calm Sea and Low Tide," with its tender and correct relations of light and shade, Mr. A. W. Walburn and expressive "The Evening Hour," "A Morning Catch," by Mr. M. L. Bodine and Miss N. F. Lewis, which is excellent in its air suggestion, and the admirable "Winter," by Mr. J. E. B. Lewis, which is particularly to be praised for its tone subtlety and judicious and expressive actuality, are all productions which themselves and do credit to the taste and skill of the workers concerned. There are others which in a less degree possess these qualities, but, unfortunately, the total number of these more valuable contributions is too small to give the collection as a whole the real amount of authority.

The Photographic Salon is not more convincing than its rival. It shows once more the inclination, with which it has been trained throughout its career, to encourage eccentricity with little regard for artistic properties. There are certainly some things, like Mr. C. H. Emanuel's spacious and atmospheric "Landscape View," Mrs. F. E. Coburn's vigorous studies, "Hammersmith" and "Reflections"; Mr. C. Puyo's "L'Etang"; the treated architectural subjects, "A Pillar of Chartres," by Mr. Evans, and "A Relic of the Past," by Mr. S. G. Kimber; and charming little figure composition, "Fair is Thy Blossom, Thy Flower," by Mr. T. Lee Syms; but these are not enough to save the society from the sin of seeking to exalt mere extravagance in position which should be reserved for inspired originality.

It gives up, unquestionably, too much of the wall space of the gallery to such works as Mr. W. Cadby's "Snow Sketch," Mr. C. Grove's "Vigil," Mr. W. Muir's "Winter," and Mr. W. B. Ton's "Evening Mists"; and it assigns prominent positions to productions of nature like Mr. Horsley Hinton's "On the Moors," and A. L. Coburn's ponderous tone study, "The Rudder," a good specimen spoiled by absence of executive refinement and by lack of intelligent management of light and shade relations. But in this misuse of opportunities the Salon only follows the lead of the Royal Society and adopts a fashion which to all appearances dominates the photographic world. That it should do so is a matter for the deepest regret; while this fashion persists photography must always remain outside the pale of the arts.

**TONING Postcards: A Correction.**—Mr. G. T. Harris writes us:—I shall be glad if you will allow me to correct an error in my article on "Toning P.O.P. Postcards," which appeared in your issue of the 14th ult. The strength of the fixing baths should be, for the first 10 per cent. and for the second 5 per cent., not 6 per cent. and 4 per cent. as given. I alone am responsible for the error, which should have been detected in the proof. I have only now glanced through the published article, when the mistake at once caught my attention.

**THE Photographic Convention of the United Kingdom.**—Mr. F. A. Bridge (hon. sec.) and Messrs. Alfred Ellis and Water Potter (members of council) journeyed to Hereford last week to confer with the local committee as to the proposed arrangements for next year's meeting. On Tuesday, the 25th ult., an interview with the Mayor at the Town Hall was followed by a well-attended committee meeting, over which Mr. Alfred Watkins presided. During their brief visit Mr. Bridge and his colleagues motored over much of the

ground proposed for next year's excursions. The towns and villages included were Ledbury, Bosbury, Weobley, Pembridge, Kington, and Abbeydore. Mr. Watkins (president-elect) drove his own car, and, being well acquainted with the locality, most enjoyable and interesting runs were made, the roads being very good and the weather splendid. Ludlow, Goodrich, and Ross have also been mentioned as possible places to be visited, and will be included in the list to be submitted to the council at its meeting on Thursday the 11th inst.

**TITLES ON Negatives.**—In reference to recent inquiries from readers, Messrs. O. Sichel and Co., 52, Bunhill Row, London, E.C., draw our attention to the "Titleit" outfit of theirs. Opaque letters are applied to the negative, and the title appears white as white on the prints. The outfit contains a large assortment of letters. Other title outfits have been reviewed under "New Apparatus."

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received from September 11 to September 22.

**WASHERS.**—No. 20,746. Improvements in attachments for taps for use in connection with the washing of photographic plates, prints, etc. Edwin Goodman, 24, Temple Row, Birmingham.

**CAMERAS.**—No. 20,781. Improvements relating to photographic cameras. Kodak, Ltd., Chancery Lane Station Chambers (for Harvey W. Locke, United States).

**PLATE-HOLDER ATTACHMENTS.**—No. 20,782. Improvements relating to plate-holder attachments for photographic cameras. Kodak, Ltd., Chancery Lane Station Chambers, London (for Harvey W. Locke, United States).

**HELIOCHROME PLATES.**—No. 20,384. Improvements in the manufacture of screens and plates for heliochrome processes. Rodolphe Berthon and Joseph Gambis, 31, Bedford Street, Strand, London, W.C.

**BORDERS ON PHOTOGRAPHS.**—No. 21,041. Improvements in means for producing fancy borders on photographs. William Tylar, Prudential Buildings, Corporation Street, Birmingham.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CINEMATOGRAPH-PHONOGRAPH.**—No. 26,522. 1905. The invention consists of synchronising apparatus—viz., a speed indicator which enables the speed of the cinematograph to be ascertained at every moment and regulated in accordance with that of the phonograph. This indicator apparatus chiefly consists of two rotating indicator hands concentrically arranged, one of which is freely and regularly operated by the phonograph, whilst the other depends on the movement given to the cinematograph in such manner that the second hand can be made to follow exactly the speed of the first, the speed of the said cinematograph thus being modified. This action can be effected either by hand or by means of a resistance when the cinematograph is operated by a mechanical or electric motor. A. J. Boulton, 111, Hatton Gardens, E.C., for Henri Joly, 94, Boulevard Jourdan, Paris.

**RETOUCHING NEGATIVES.**—No. 24,816. 1905. The invention has for its object the simplifying of that part of the work known as knife work, which consists of cutting away or thinning portions of the film to make corrections in the picture, which is usually done by a sharp knife. It consists of a composition composed of fine cutting or abrading powders, in fine division, combined with various waxes or similar substances to form them into a solid substance, which can be compressed or moulded into convenient shape for use as a crayon or pencil, and be sharpened to a point so that it can be used as an erasing point. These moulded and pointed substances are used in conjunction with a lubricant which is called a medium, and which is composed of various fine thin oils, such as paraffin, turpentine, and the like, or a mixture of them. This medium is smeared on the parts of the negative to be worked upon, and the work is then executed by means of the pointed substance, which is worked with a delicate rubbing motion and removes the surface as much as is required, instead of cutting or shaving off the same with a knife. James William D'Anter, 4, Villas-on-Heath, The Vale, Hampstead, N.W.

**LANTERN SLIDE PRINTING FRAMES.**—No. 22,898. 1905. The invention is a frame permitting of accurate adjustment of the negative of the lantern plate, so that horizontal lines are so rendered in the lantern slide. A main board, having a square aperture in it, is hinged to a frame with like aperture, which, when clamped together, hold the "negative" between them, the frame allowing the passage of a lantern plate to the back of the "negative." To the main board is hinged a door, which swings

to the back of the frame, excludes the light from the rear, and presses the lantern plate into contact with the "negative" in the usual way. A frame holding a ruled screen of glass, which may be fixed rigidly at right angles to the hinged door, so that when the latter is swung away from the back, the ruled screen comes into position in front of the main board, to allow the adjustment of the "negative" to the lines on the screen. To enable the printing frame to fold into compact form, the door and ruled screen are hinged to the main board in line, and supported at right angles to each other by suitable catches or clamps. The ruled screen may be fitted in the door, may slide across the square apertures in the printing frame, or may be placed in position temporarily, and removed therefrom during exposure. The screen may be hinged or pivoted to any desirable portion of the printing frame in any suitable manner, and may consist of glass or other suitable material, with ruled, cut, or otherwise formed lines, or may be constructed of wires, cords, or the like stretched across a frame. The invention may take the form of a T-square or straight-edge, sliding across the square apertures, such as springs, pins, stops, or catches.—George Russell Nicholls, 48, Crescent Road, South Norwood Park, S.E.

## New Books.

"Jahrbuch für Photographie und Reproduktionstechnik." 1906.

Edited by Dr. J. M. Eder. Halle: W. Knapp. 8s.

Dr. Eder's "Yearbook," in reaching its twentieth issue, shows an increase in the text pages of over 100, the volume now running to page 688. As in previous years, the contents consists of original articles on photographic science or industry, and a classified abstract of contributions to photographic progress during the year. There is also a list of the new books of the year and of German photographic patents. With these must be mentioned the very full index of authors and subjects, the two occupying 32 pages. Dr. Eder and his staff are to be congratulated on the production of another issue of this great work, which is, if anything, too encyclopædic and comprehensive. To the more recondite branches of photography, such as photo-chemistry, Russell effects, spectroscopy, Dr. Eder is prepared to devote a number of pages, which in this country would seem out of proportion to the number of persons able to make use of such information. Our own feeling in preparing the "Epitome of Progress" in the BRITISH JOURNAL ALMANAC, is, that such persons may be presumed to have the original articles for their reading. The first portion of the "Yearbook" includes the following on colour-photography:—

"The Bleach-Out Process," by Dr. Neuhaus.

"New Investigations in the Lippmann Process," by Dr. Hans Lehnmann

"The Young-Helmoltz Theory of Colour and Colour-Photography," by Dr. L. Pfandl.

"Coloured Illumination in Three-Colour Photography," by William Gamble.

Among other noteworthy papers may be mentioned one or two others, though they do not by any means exhaust the list:—

"The Preservation of Gelatine Emulsions in Milk," by Dr. Homolka.

"Yellow, Orange, and Green Tones on Bromide," by Prof. R. Namias.

"The Cause of the Special Action of Hypo in the Developer," by Dr. Lüppo-Cramer.

"Stable Sulphite Solutions." W. Weissenberger.

"Silver Phosphate Emulsions," by E. Valenta.

A word should be said for the supplements, among which are an example of Spitzertype, in four colours, machine collotype, and many specimens of half-tone and photogravure printing.

"Simple Photographic Experiments" is the title of a small book, published by Messrs. Percival, Marshall, and Co., 26-29, Poppin's Court, London, E.C., for the sum of 6d. It forms one of the well-known series of handbooks, the publication of which is in the

capable hands of our contemporary, "The Model Engineer." In the present volume Mr. Thorne Baker has been persuaded to interest the engineering student in the technique of photography. His chapters are devoted to the processes of emulsion making, paper manufacture, the gum process, orthochromatic plates, enlarging, lantern-slide making, and elementary photographic optics. Though not intended to be in any way a handbook to these branches of photography, the book will no doubt answer its avowed purpose of introducing its readers to experiments in the essential processes of photography.

## New Apparatus, &c.

The "Sickle" Mercury-Vapour Printing Apparatus. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

This new introduction of Messrs. Sichel is opportunely placed on the market at the commencement of the winter season, and should therefore particularly merit the attention of professional photographers and printers. The apparatus utilises the now well-known mercury-vapour light, the suitability of which for the purpose, owing to its great actinic power and absence of heat, is no doubt widely appreciated. The printing outfit is sold in two sizes, the smaller enclosing one lamp and the larger, shown in the drawing, three. The single-tube installation accommodates twelve

half-plate printing frames; the larger apparatus has the advantage that it can be employed for large and small frames, having a capacity of twenty-four half-plate frames or a smaller number of larger ones, and *vice versa*. Although placed close to the tube, the equality of the light over the frames is remarkable, and the heating is practically nil. The speed of printing is from ten minutes on

P.O.P., according to the density of the negative, but with time, which is that for a clean, quick printing negative, the cap of the apparatus is quite sufficient to keep a printer busy. The needed current, which must be continuous, not alternating one-half unit on a 200-volt circuit per hour, representing a of running which prospective purchasers can work out for themselves from the day charges for their local supply. The construction of the apparatus is convenient and compact, and we have doubt that Messrs. Sichel will find many customers among professional classes. The price of the installation, complete lamps, resistances, and induction coil, is £6 10s. for the one-size and £11 for the three-tube. Extra tubes cost 30s. each.

The Aldis Anastigmat, Series II., No. 2A. Made by Aldis B. Old Grange Road, Sparkhill, Birmingham.

This lens is of 6.4in. focal length, and is designed to work at  $f/6.3$  when mounted in a Bausch and Lomb 5 by 4 Unicum Automat shutter. Though included in the well-known Series lenses, which work at  $f/6$ , we understand that the 2A lens is a modified design. It has been produced especially for use in a card-size camera, and it should fulfil this purpose excellently, considering that our tests in a half-plate gave most satisfactory results. A trial on a plane test chart showed that it covered a half-plate well at  $f/6.3$ , and that the definition at the corners was all that could be desired with such a large aperture. A more critical test on a small point of light shows that the astigmatic correction is of a high order, the trace of astigmatism and coma being very slight indeed. It may, perhaps, be as well to note that such traces nearly always to be found even with the highest-class lenses, that such a test as this readily reveals aberration, even when the amount is so small as to be quite negligible in practical work. Tests on normal subjects show that the lens is a most useful one for anything up to half-plate, and, considering its low price, should be a very popular instrument. When stopped down, it covers a fairly wide angle, and, obviously, it should be useful as a wide-angle lens with fairly large plates, though we have not actually tested it on any bigger than a half-plate. The lens is small, very light, weighing in plain brass mount only  $3\frac{1}{2}$ oz. Comparing with another anastigmat of the same aperture and 7in. focal length (only .6in. more), we found the difference in weight to be no more than  $7\frac{1}{2}$ oz., or close on  $\frac{1}{2}$ lb. Such differences are of considerable importance with lenses designed for rapid work in hand cameras. With regard to the Aldis mount, we should like to suggest that an index mark to which the diaphragms are adjusted should be bolted. At present it is a little difficult to find. The price of 6.4 focus is £2 2s. 6d., in iris mount.

PORCELAIN Dishes.—Messrs. Houghtons, Ltd., 88-89, High Holborn are issuing a new series of dishes, which are the result of some considerable pains on their part to obtain a dish, the design of which would be an improvement in strength and convenience on the existing patterns. The dishes, which are the result of their labours, are known as the "Ensign," and are to be marketed at the standard prices as follows:—

Inside Measurement.	Shallow. Each.	Deep. Each.
$4\frac{1}{2} \times 3\frac{1}{2}$ .....	0s. 6d. ....	0s. 7d. ....
$5 \times 4$ .....	0s. 7d. ....	0s. 8d. ....
$5\frac{1}{2} \times 3\frac{1}{2}$ .....	0s. 7d. ....	0s. 8d. ....
$7 \times 5$ .....	0s. 10d. ....	0s. 11d. ....
$9 \times 7$ .....	1s. 2d. ....	1s. 5d. ....
$10 \times 8$ .....	1s. 5d. ....	1s. 8d. ....
$12 \times 10$ .....	2s. 3d. ....	2s. 9d. ....
$15 \times 12$ .....	5s. 0d. ....	6s. 0d. ....
$18 \times 14$ .....	9s. 0d. ....	12s. 0d. ....

In many respects the dishes meet with our approval. The bottom is flat instead of possessing the annoying bulge, which prevents the plate from lying flat in many dishes; there is a narrow channel at the end of the dish, which permits of the plate being readily removed; the rim round the base of the dish prevents sticking to the developing bench; and last, but not least, the dish is strengthened at the corners by thickening of the material. Mechanically, the dishes seem excellent, and we are glad to have Messrs. Houghtons' assistance that, in addition to its good qualities in these respects, the material withstands the action of alkaline and other solutions.

failure of cheap developing dishes to retain their glaze, even when used for water only, is a source of dissatisfaction, which doubtless many of our readers have experienced. The "Ensign" dishes should be welcomed if they preserve the natural surface of the enamel.

## New Materials.

"Argo" Gaslight Papers. Made by the Defender Photo-Supply Company. Sold by A. E. Staley and Co., 19, Thavies Inn, London, E.C.

In announcing to us the introduction upon the British market of the manufactures of the Defender Company, Messrs. Staley send us samples of the Argo (gaslight) papers, of which no less than twenty-four varieties are made by the American Company, though not all of these, our dealer friends will be glad to hear, are to be marketed in this country. As representative of the papers, we may describe the brands designated by the names "Carbon Velours," "Portrait Argo Matte," and "Carbon Argo." These we find to afford a pleasing variety in surface. The "Carbon Argo" is a fine matt paper, the "Portrait Argo" is one of a series of papers for soft effects and for contrasting negatives, and "Carbon Velours" is a paper with a slightly lustrous surface resembling albumen.

The different effects obtainable should satisfy the printer that a negative must be outside the very widest limits if an Argo paper cannot be found which will give a presentable print upon it. The necessary developing preparations are supplied by Messrs. Staley, from whom a full supply of the papers will be almost immediately obtainable. Dealers should apply to Thavies Inn for further particulars and scale of discounts.

THE Adhesive Dry Mounting Company, Limited, 27 and 28, Peter Lane, London, E.C., notify us that in consequence of the completion of their factory in Hackney for the making of the adhesive tissue, etc., they are able to reduce the prices as below:—

	Old Price.		New Price.	
	2s. 2d. per gross	1s. 6d. per gross	2s. 2d. per gross	1s. 6d. per gross
Quarter-plate .....	3s. 3d. "	2s. 6d. "	3s. 3d. "	2s. 6d. "
5 by 4 .....	3s. 6d. "	2s. 9d. "	3s. 6d. "	2s. 9d. "
5 by 4 1/2 .....	4s. 6d. "	3s. 3d. "	4s. 6d. "	3s. 3d. "
Half-plate .....	6s. 6d. "	5s. 0d. "	6s. 6d. "	5s. 0d. "

15 by 12 .....	52s. 0d. "	45s. 0d. "	52s. 0d. "	45s. 0d. "
20 by 24 .....	10s. 6d. "	7s. 6d. "	10s. 6d. "	7s. 6d. "
20 by 24 .....	10s. 6d. "	7s. 6d. "	10s. 6d. "	7s. 6d. "

## CATALOGUES AND TRADE NOTICES.

From Messrs. R. J. Moss and Co., Constitution Hill, Birmingham, we are in receipt of a booklet containing a good deal of advice on the management of the acetylene light. The publication also embodies a price list of the leading requisites for the generation and use of acetylene, and should form a useful reference volume to those contemplating the purchase of an acetylene installation for enlarging or projection purposes.

"How Can I Enlarge?" Under this title Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C., have produced an attractively got-up booklet, which imparts the elementary principles concerned in the making of a bromide enlargement in a commendably agreeable manner. The booklet includes prices and illustrations of the firm's various enlarging apparatus, and is supplied to dealers with their name printed on the front cover. Those intending to obtain the full value of the winter trade in these articles should get it worth their while to apply to Messrs. Butcher.

The Boardman Electrical Patents Company, Limited, send us their latest list of open and enclosed arc lamps for portraiture and printing. It gives particulars of their standard lamps and of a new installation produced (at a popular price) for both studio work and P.O.P. print-

ing. Application to 10, Southwark Bridge Road, London, S.E., will bring this list.

No. 3 of "The Professional Photographer" (Kodak, Ltd.) reaches us, admirably printed, and containing seasonable literary fare in the shape of articles on "Portraiture in Winter," "Christmas Trade," etc.

MESSRS. BUTCHER AND SONS, Camera House, Farringdon Avenue, E.C., are drawing attention to their cinematograph department by the issue (for the first time) of a special catalogue of their cinematograph goods. The list runs to sixty-four pages, and includes, in addition to particulars of projectors, films, and accessories, details as to Messrs. Butcher's hire department.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
6.....	Worthing Camera Club.....	Outing to Shoreham and Southwick.
6.....	L.C.C. Staff Camera Club.....	Outing to Wimbledon Common.
6.....	Aberdeen Photo. Art Club.....	Outing to Bishop Loch.
6.....	Southampton Camera Club.....	Slide Criticism Competition.
8.....	Luton Camera Club.....	"Practical Oil Printing." G. H. Rawlins.
8.....	South London Photo. Society...	"Lantern Slide Making." C. H. Oakden, F.R.P.S.
8.....	Lancaster Photo. Society.....	"Development of P.O.P." Fred Hargreaves.
9.....	Leeds Photographic Society...	"The Land of the Vendetta." Chas. B. Howdill.
9.....	Keighley and Dis. Photo. Assn.	"The Making of Lantern Plates and Slides." F. Brundrett.
9.....	Darlington Camera Club.....	"Enlarging." Demonstrated. C. J. Barthorpe.
10.....	Croydon Camera Club.....	"Making Transparencies for Enlarged Negatives." F. W. Hicks.
11.....	North London Photo. Society...	"What is a Good Negative?"
11.....	London and Prov. Photo. Assn.	"A Scientific Chat." A. Haddon.
11.....	Dumfries and Maxwell's P.A.	"First Annual Photographic Exhibition and Competition."

THE CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY commence their winter session on Monday, October 8. The Secretary (Mr. W. T. Browne, 169, Woolstone Road, Forest Hill) will be pleased to send any information to our readers or to hear from intending members.

THE BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—At the annual general meeting held on September 26 last, the hon. secretary's annual report showed that the society was in a sound financial condition, and that the past year's works had been very satisfactory. A very comprehensive syllabus has been arranged for the coming session, including lectures and papers by some of the leading workers of the day, and a series of practical demonstrations, which beginners will find very useful and instructive. Meetings are held every Wednesday, at the Institute, 103, Borough Road, S.E., at 8 p.m. Applications for membership from ladies and gentlemen, amateurs or professionals, are cordially invited, and should be addressed to the Hon. Sec., Mr. F. Harrop, 7, Boveney Road, Honor Oak Park, S.E., or at the Institute.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held on the 27th, Mr. Briggshaw in the chair, the members were entertained by a very special and enjoyable lecture by Mr. A. L. Henderson, upon "Madeira Up to Date." Madeira, he said, was about thirty miles long by some fifteen miles wide, and very hilly, the usual manner of ascending the hills being either by rail or by means of what could only be described as a hammock slung to a long pole and carried by two men. In his own case it was four with double charges, and the descent was usually made by means of a sledge, which ran freely over the cobbles with which the roads were made, the men holding on the two ropes and thus acting as brakes. In all, Mr. Henderson showed some 150 exceedingly fine slides, many of them being panoramic. Slides were also shown of the special lepers' hospital and the lepers and their attendants. A hearty

vote of thanks brought to a close all too soon a very interesting evening.

**SOUTHAMPTON CAMERA CLUB.**—The members of the above gave a very warm welcome to the Rev. H. W. Dick, of Manchester, who lectured to them on Monday, October 1, on photographic work "in field and dark-room." In quiet conversational fashion the lecturer produced from his storehouse of practical experience many points of interest and instruction, and demonstrated many possibilities in the pursuit of the art. At the outset he warned the workers not to fall into the habit of charging their failures to their apparatus, nor to attribute their lack of progress to want of expensive instruments. He stated in emphatic terms that with an inexpensive yet suitable camera, and an equally inexpensive but R.R. lens, the best pictorial results were open to the enthusiast. After pointing out the varying spheres of usefulness of the stand and hand cameras, he referred to some difficulties connected with the latter. The difficulty of focussing in hand work he suggested might be better dealt with in the following way, which he used: The focussing scale should be subdivided into smaller distances by careful records made thereon after accurate measurement; then, instead of guessing at the distance of an object to decide at what distance it could be best dealt with, focus the camera and step out the distance. With moving objects, as in figure studies, the camera should be focussed for a given distance, and the worker should preserve that distance instead of standing still and making a guess when the pose was right. The lecturer pointed out that the difficulty of preserving sharpness in both foreground and distance could be met by the tilting of the swing-back, a fact not generally recognised. Mr. Dick pleaded for the use of isochromatic plates and screens in hand-camera work, alleging that the advantage of these aids might be obtained even in October at the best hours of the day by anything like a 1-25 at  $f/8$  on a special rapid plate. Among dark-room matters one point was made much of—viz., that to force an under-exposed plate must always be fatal for the pictorial worker, since if detail were obtained in the shadows the high lights would certainly be spoiled. The rule given was "expose for shadows, develop for high lights." A most cordial vote of thanks was passed by a most appreciative audience.

## News and Notes.

**ROYAL Photographic Society.**—We regret to hear that in consequence of General Waterhouse's illness, he will not be able to give his presidential address next Tuesday, Oct. 9. In place of that, descriptions of the spectrophotometer, comparison photometer, wavelength spectroscopic, and the various photometers now on exhibition in the balcony of the New Gallery, and other apparatus in connection with their use, will be given by Mr. C. E. Kenneth Mees, B.Sc. Mr. C. Welborne Piper will also describe his models of light pencils, showing various effects of aberration, and Mr. E. J. Wall will deal with Mr. Edgar Senior's Lippmann photographs.

**R.P.S. LECTURES.**—The following lectures will be delivered at the New Gallery:—

Saturday, Oct. 6, "Limestone Marvels of the Subterranean World." (The interiors of the caves will be shown on a patent crystalline screen, the invention of the lecturer). By F. Lambert, F.R.G.S.

Monday, Oct. 8, "Our English Chapter Houses," by E. W. Harvey Piper.

Thursday, Oct. 11, "A Trip to the Victoria Falls of the Zambesi," by John F. East.

THE Congress of "Photographic Record," recently announced as to be held in France, will take place at Marseilles, in the Hall of the Colonial Exhibition, on October 19, at 2 o'clock. Particulars of the railway facilities, etc., may be obtained from the secretary, 51, Rue de Vichy, Paris.

THE Southampton Camera Club are continuing their custom of issuing a pocket-book for their members' use. The present issue, just published, is, as before, a permit to photograph in certain places in Hampshire. It contains also the Society's programme for the forthcoming session. Members are to be congratulated on a list containing the names of Arthur Marshall, Harvey Piper, Harold Baker, W. L. F. Wastell, W. Farrel, C. H. Hewitt, and

C. B. Howdill, all of whom, with others, are to lecture before Society.

**LONDON and Provincial Photographic Association.**—On October 1, Mr. A. Haddon will give a scientific chat at the usual meeting, The White Swan, Tudor Street, E.C., at 8 p.m. Visitors are welcome at the London and Provincial Photographic Association.

**M. TANQUEREY Again.**—The following letter appeared in the "Constitution" for September 25:—"Sir,—I wish to state, for information of your readers, some time ago I received a letter from A. Tanqueray, artist, 23, Rue de Hambour, Paris, stating that I filled in the enclosed coupon and sent with it a photograph of myself, which I did, he would forward by return a beautiful portrait, absolutely free. That, unlike other artists, he was asking me to take a frame from him. When next I heard from him it was to send on ten shillings, when he would then forward me a crayon portrait. I wrote to tell him that he made no stipulation and he has taken no notice of my letter. I merely write as a warning to others who may be tempted to do likewise.—Yours, etc., F. H. DAUNT, Carrigaline, September 21, 1906."

**SHOULD Have Been Full Length.**—An amusing story of how Preston Guardians were once surprised was told last week, when a Liverpool lady, applying for a position as charge nurse, forwarded a photograph, saying that she could not come owing to a desire to see the family. Once before, said a guardian, they appointed a candidate who forwarded a photograph, and on her arrival she was found to have a wooden leg.

**THE Sensation of Electrocuting.**—A delightful compliment has been paid the photographic process in the course of a murder sentence in New York. The mystery of the murder of an Armenian has been solved by the identification of his dismembered body, and the confession by his brother, Aram Tashjian, that he slew him. The brother was arrested Aram on suspicion. While he was seated in a chair photographed for the Rogues Gallery, Aram became terrified, thinking it was the electric chair, and he admitted everything.

THE prize of £1 10s., offered by Messrs. Growers, Ltd., for the best photograph of the Malden marine lake has been won by H. H. Taylor, an engine driver on the Malden and Witham Gas branch.

**PHOTOGRAPHIC Trade in Italy.**—The current "Board of Trade Journal" reports that in the import of cameras, lenses, photographic plates, films, etc., there is keen competition with America and Germany, but principally with the latter, on account of their cheap prices and the facilities they give as to credit, which is an inducement to the dealers to recommend German-made articles. British-made articles are, however, in great demand on the part of tourists, and a pretty good trade is carried on. British camera manufacturers should endeavour to meet the wishes of local importers, as far as may be possible, and send out travellers with cheap patterns; their apparatus should be accompanied by proper instructions in the Italian language.

An enthusiastic amateur photographer has passed away in the person of Mr. J. A. Prout, of Park Grove, Bromley.

At Cilfynydd last week, Luke W. Proud, photographer, and another D. Rosser, Pontypridd, were brought before an occupation police court, the former charged with using a room for the purpose of receiving bets, and the latter with resorting to a place for the purpose of betting. Inspector Salter, who watched Proud's premises for a few hours, stated that he entered the premises with a warrant and upon both men were found betting slips. The presiding magistrate said he thought the defendant had been the dupe of a man. A fine of £7 was inflicted in each case—£21 in all—on months' imprisonment.

**BELFAST Central Camera Club.**—The annual meeting of this club was held on the evening of the 28th ult., in the club rooms, Assembly Buildings, Mr. A. A. Shaw presiding. The secretary's report was a most satisfactory one, and showed the club to have made considerable progress both in membership and work done. The treasurer submitted an equally pleasing financial statement, showing a balance in hand. It was decided at the meeting to fit a first enlarging apparatus (large enough to take whole-plate negatives) in the dark room, and a special effort is being made by the club to have this done as early as possible.

## Correspondence.

- \* Correspondents should never write on both sides of the paper.  
 No notice is taken of communications unless the names and addresses of the writers are given.  
 \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PHOTOGRAPHIC RESEARCH.

To the Editors.

Gentlemen,—I shall be glad if you will kindly find room for the following announcement:—

The Council of the Photographic Convention of the United Kingdom is prepared to make grants of money in aid of photographic research.

#### CONDITIONS.

- (1) An applicant for a Research Grant must present (a) a concise statement of the general nature of the proposed investigation and its object, with an abstract of any results that have already been obtained, and (b) a general statement of the way in which it is proposed to expend the Grant.
- (2) A Grant must not be expended on the purchase of permanent pieces of apparatus except by special permission of the Research Grants Sub-Committee.
- (3) The receiver of a Grant must make a general report of expenditure, either at the end of, or during the progress of, the research, and shall then be entitled to receive either the whole grant, or such part of it as may have been actually expended.
- (4) The receiver of a Grant must present a full report on his investigation at the first meeting of the Convention after the research is finished, and an interim report at any intervening meeting. If necessary, in order to secure priority of discovery or intervention, the results may at once be published, by communication to such recognised national, scientific, or photographic society, as the Research Grants Sub-Committee may decide.

Thanking you in anticipation, I remain, gentlemen, your truly,  
 F. A. BRIDGE,

Hon. General Secretary and Treasurer.

East Lodge, Dalston Lane, London, N.E.  
 September 28, 1906.

### THE SENSITOMETRY OF PLATES.

To the Editors.

Gentlemen,—In reply to Mr. Gascoigne's letter of the 28th, if a light be taken, which is too rich in green or red compared with blue and violet, then this excess can clearly be removed by means of a bluish-violet screen, and if any particular wave-length be taken as the standard a screen can be made which will render the adjustment right throughout the spectrum up to that wave-length, provided that any light of that wave-length is present at all. This may be made clearer by a reference to the figure. Suppose A is the curve of sunlight intensity against wave-length and B the curve of acetylene. Then the use of our filter will reduce the curve of B to that shown as C. These curves are not intended to be accurate, but illustrative. For the accurate curve see "Photographic Journal," March, 1906, and November, 1904.

It is seen that between 6,700 and 3,700, the correct acetylene curve is the same as sunlight, though of lower intensity than that shown as curve A. Possibly this correction should be extended below 3,700, but this is very difficult to do.

The intensity of the light source used is of no importance, because, after reduction to the correct spectrum curve, it is standardised by photographic comparison with a standard pentane lamp upon an ordinary plate.

Thus the standard pentane is taken as an actinic standard, not a visual one. If a light screened by Eder's potassium chromate were standardised in the same way then an ordinary plate exposed behind it would give the correct inertia. It may be well to state that the screen given by us is unsatisfactory in some ways, notably as regards

permanence when made as a gelatine screen. I cannot spare time at present to re-investigate it, as I should like to, with the new red sensitive plates; perhaps some one else can.

As regards fog, the answer to Mr. Gascoigne's question is, that if the fog is high he cannot rely on his readings, and cannot get the true inertia. But there are very few plates on the market in which the fog is great enough to cause an appreciable error if care is taken in working. In the case given by Mr. Gascoigne of a fog of .22, the error is negligible, and the speed might be safely taken as 200. The fog must be deducted. In some of H. and D.'s experimental

plates, however, the fog error is very serious, and in our own work, when working with thiosulphate in developers, or developing for twenty-four hours for  $\gamma\infty$ , fog was the great trouble, and by far the greatest source of error. Mr. Gascoigne will note that it was in photo-chemical investigation that we laid stress on the necessity for very fog-free plates.—Yours faithfully,

C. E. KENNETH MEES.

Croydon.

### REFLEX CAMERA MOVEMENTS.

To the Editors.

Gentlemen,—In your last issue Mr. H. G. Ponting, under the heading, "A Hint to Makers of Reflex Cameras"—the idea of a swing back—it may therefore be news to him that I some months ago, to be exact, on March 9, applied for a patent for the addition of a swing back to reflex cameras, and, as my full specification is now in the hands of the Patent Office officials, I hope soon to have the same upon the market. Mr. Ponting appears to have given some thought to the subject without success, and I, after some long, and perhaps rather tedious, experiments, at last hit upon the plan which is now under patent arrangements, and discovered a means of moving both the focal-plane and the plate, the finder, ground glass, and the mirror in unison. You, gentlemen, shall see the camera as soon as complete, or, if you care to, you can, at any time, even now, see my rough model, which undoubtedly will be sufficient to show you the movements.—Yours very faithfully,

ERNEST HUMAN.

43, Whitta Road, Manor Park, Essex.

To the Editors.

Gentlemen,—Having read with interest Mr. Ponting's letter on page 777 of your last issue, we are pleased to inform you that we have already fitted our well-known "Videx" with the complete extra movements he asks for, and in such a perfect and simple manner as would probably surprise him.

With this letter we are submitting a half-plate "Videx" fitted with our new horizontal and vertical four-way swing-front for your inspection, feeling sure that you will be sufficiently interested to appreciate what we have accomplished, and thus be able to inform your correspondent that his stated requirements can be most fully met.

Mr. Ponting says:—"The manufacturers who put a well-made half-plate reflecting camera on the market, embodying the triple

movement of rising front and vertical and horizontal swinging lens, will secure my order at once, providing the camera has the usual qualifications of long focus and reversing back as well."

We can assure him he may place such order with us with confidence, as it is for such capable and practical workers as himself that we specially cater, and the high appreciation we have received from press and public, and which now number many hundreds, prove sufficiently encouraging to us to persist in turning out the finest and most complete instruments that our capabilities and long experience in this class of work enable us to do.—Yours faithfully,

26, Charing Cross Road.

ADAMS AND CO.

[The movement referred to Messrs. Adams has the great practical advantage of automatically bringing the lens "square with the plate." It provides up, down, and sideway tilt of the lens, and appears in every way to respond to our correspondent's requirements.—Eds. B.J.P.]

#### To the Editors.

Gentlemen,—The letter on p. 777 of last issue is, I venture to think, well worth the attention of reflex camera makers, and there is also one other point which I think is worth notice. Why is it necessary to put the ground glass focussing screen flat on the top of the camera? This necessitates craning the neck over the camera in a decidedly uncomfortable position, whilst if the screen was set at a slight angle, the angle of the mirror, of course, being likewise shifted, it would be much easier to see the image on the ground glass.

Whether it would increase the size of the camera or not I cannot say, but it ought not to, because it should be easy to arrange for the ground glass to be pivoted at the edge nearest the user, and thus enable it to be depressed flat when not in use and be covered by the light hood in the usual way.

The normal position of holding a book or paper to read is about 25 to 30 degrees from the horizontal, and this would, I think, be about the correct angle for the focussing screen.

There might possibly be some optical objection to altering the angle of the mirror, but on this I cannot speak.—Yours faithfully,

F. BELL.

Glasgow, September 30, 1906.

#### THE RETURN OF SPECIMENS.

##### To the Editors.

Gentlemen,—I often wonder if it is necessary to keep a man waiting some two or three, and sometimes four, weeks for the return of his specimens which have been sent in answer to advertisements. Surely it does not take a man all that time to make up his mind which operator he will try. I sent my specimens some three weeks ago, and up to now have not received any reply. The result is I am not able to answer other advertisements for want of specimens. This is very hard on a man who depends on samples of his work to get an engagement.—I am, yours faithfully,

ASSISTANT OUT OF WORK.

#### THE STABILITY OF PYRO AND SODA DEVELOPING SOLUTIONS.

##### To the Editors.

Gentlemen,—In your interesting notes on my article in the *BRITISH JOURNAL OF PHOTOGRAPHY* of September 23, pages 762 and 766, there are two points on which I would ask your permission to comment.

You say "Mr. Bennett's idea of a stainless negative evidently differs from ours. In the latter part of his article he refers to the composition of the developer not being favourable to the production of a pure black tone, which idea is just the one that we endeavoured to combat in our former note. The brown-coloured image to which he refers is not a necessary consequence of using pyro, which, with properly devised formulae, gives as black and as clean an image as metol or any of the new developers, and does so without the aid of an acid or any other special kind of fixing bath. Such images cannot well be obtained with formulae in which the sulphite and carbonate are mixed together, on account of the rapid deterioration of the sulphite." The italics are mine.

There appears to be a misunderstanding. In writing that it was

"necessary to discriminate between a negative that is brown as a consequence of the composition of the developer not being favourable to the production of a pure black tone, and one that is stained," I wished to refer to those cases in which a brown image is produced, as in transparency making, though the plate is absolutely stainless. If a slow negative plate is used for making a transparency, and considerably over-exposed, and the same developer is employed that would produce a pure black tone in ordinary negative work with the addition of a large proportion of bromide, the image will be brown instead of black, but quite free from stain as under normal conditions. By using a chlorobromide plate, as in lantern-slide making, a very warm brown almost a red, may be produced by the normal pyro developer by simple addition of a bromide. My reason for this distinction is the fact that photographic workers and writers have confused colour with pyro stain, which is incorrect. This colour is due to a difference in the deposition of the silver forming the image, and with a decomposed developer the gelatine film is stained.

In the press and at meetings of photographic societies I have always contended that a pure black tone should be the aim of the photographer in negative making. And this is, in reality, the sole reason of your comments, and of my article. Equally strongly as you, I advocate the pure black and stainless negative, but there appears to be a radical difference in our conclusions from our experience.

You state, page 762, "that a stale compound solution of sulphite and carbonate, only three months old, acted in precisely the same way as a fresh solution of carbonate alone. This amply proves the sulphite practically disappears in the alkaline solution in short time."

This is the crucial point at issue, as it is impossible to reconcile your experience with mine. Used in conjunction with a pyroton containing half-a-grain of potassium metabisulphite to a grain of pyro, a plain solution of sodium carbonate would give very dirty and stained negatives, while a solution containing equal parts of sulphite and carbonate has invariably produced stainless plates. At times my photographic work becomes very intermitting and then solutions are kept, but no difference in quality of working is apparent. My negatives are a good black colour, always free from stain. And no clearing bath or acid fixing solution is ever used. They are fixed in clean hypo only. The alkaline solution invariably used contains equal quantities of sodium carbonate and sulphite. It is the experience of years of working with these solutions that has led me to form the conclusions expressed in my article. The combined solution of carbonate and sulphite has never, in my work, acted like a simple solution of carbonate. At times a plain solution of carbonate, or a smaller proportion of sulphite has been used for experimental purposes, and inferior stained negatives have always been the result.

The importance of this subject will, I hope, be considered a sufficient reason for this long communication.—I am, sir, yours truly,

HENRY W. BENNETT.

Ilford, October 1, 1906.

##### To the Editors.

Gentlemen,—The articles on the sulphite in the developer interested me at the present moment, and lead me to ask a practical question for myself, which perhaps you or some of your correspondents will kindly answer. I am only an amateur and able to work at photography only at intervals. After a period of five years I have again got out my apparatus. I used at first a pyro developer, which I often used before, mixing it generally at short intervals. As much of my work is experimental I resolved to try again the hydroquinone and the eikonogen, as shown below, developers with which I had scarcely any experience, and to use one or the other separately or both combined, according to circumstances. I used it with a series of exposed films of different makers, applying first the hydroquinone and adding the carbonate and the eikonogen, rather more diluted than the formula indicates. The films which would have proved over-exposed with the pyro were by no means so with the developer. It was perhaps too much diluted. I have adopted this form for several reasons, and, among others, because these develop-

spoken of as being very stable, and it will be a great convenience to have such as I may at any time depend on, without the need of making them up afresh; also it is said that they may be used several times over.

## HYDROQUINONE.

Aq. ....	1000 c.c.m.
Soda sulphite .....	75 gms.
Hydroquinone .....	10 gms.
Crystallised soda carb. ....	150 gms.

## EIKONOGEN.

I. Aq. ....	1000 c.c.m.
Eikonogen .....	16 gms.
Soda sulphite .....	70 gms.
II. Aq. ....	1000 c.c.m.
Soda carb., crystallised .....	150 gms.

A little bromide was added in some of the developments. This brings me immediately to the point I wish more especially to inquire about—the previous explanation showing the exact position of things. As I developed each film in the manner mentioned above, I poured the mixed developer into a red well-stoppered bottle, and took from this to develop the next set of exposed films. For each one I found that it would not develop until I added from the unused developers, the eikonogen more specially, and then only with difficulty, as if it had been much over-exposed. I thought it likely, from previous experience, that it had been over-exposed, and when at last they were fixed, etc., they did not at all present the appearance of having been under-exposed. Since reading the explanations in the JOURNAL, I ask myself:

1st. Whether the hydroquinone developer is not so stable as represented; whether the soda carbonate has acted on the sulphite in the manner described?

2nd. Whether, in the developer mixed and used in the way I have mentioned, the soda has had a still more deteriorating influence? 3rd. Whether it would be necessary, or at least better, to keep the soda in the first formula separate till the moment of development?

4th. In what other way I could modify these formulæ so as to have a purpose of having a developer that will keep good for a long time and be ready whenever I want to use it? To meet the case of different plates, different subjects, and different exposures, I wish to have at my disposal the qualities of the hydroquinones of eikonogen, or of the two combined, and I want them, with a little necessary modification, to serve for bromide papers also. I wish further on substitute metol or amidol for eikonogen.

I shall perhaps mention that in developing some of the first set of films, I used a little bromide also. I shall feel much obliged for information that may come to me through the answer to this inquiry, and remain, dear Sirs, faithfully yours,  
W. WASHAM.

Ulla Cornelia, Chemin de Villard, Lausanne.

October 1, 1906.

Dr. HALL EDWARDS, who was one of the very first pioneers in X-ray work, and has employed the rays for medical work ever since, suffering from severe dermatitis, and his condition, as communicated to the "British Medical Journal," should be a warning against the indiscriminate use of the Röntgen rays. Mr. Edwards writes: "Despite all methods of protection, my hands are steadily getting worse. I have not experienced a moment's freedom from the pain for more than two years, and at times the pain is so severe that I am rendered absolutely incapable of work, either mental or otherwise. In the cold weather I am unable to dress myself, and the pain experienced cannot be expressed in words. On the back of each hand I have from fifty to sixty warts, many of them confluent. In order to excise these it would be necessary to remove the whole of the skin from the backs of the fingers and from the greater portion of the hands. The excruciating, ever-present pain appears to be due to permanent irritation of the cutaneous nerves, which nothing soothes, and which is intensified by holding the hands in a dependent position and by cold. The pain is of a neuralgic character, it never ceases, and is intensified from time to time by sudden stabs and jumps of such severity as to make one cry out. . . . In conclusion, I adjure those engaged in X-ray work to protect themselves before it is too late."

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

R. S. Cumming, 131, Fore Street, Exeter. *Photograph of the Opening of the Electric Tramways in Alphington Road, Exeter.*

Miss F. M. Buxton, 82, Balham Park Road, London, S.W. *Photograph of Miss E. Buxton.*

C. C. Smith, 1, Norman Place, Lincoln. *Photograph of the Lincoln City Football Club team of 1905-7.*

**RESIDUES.**—Can you tell me how to deposit washings from P.O.P. prints (not hypo)? I use salt, but with very little effect—in fact, from washings from some paper there is no deposit; the water remains transparent, no matter how much salt is thrown in. **RESIDUE.**

In place of salt try hydrochloric acid. Some P.O.P.s contain but little soluble silver salts, so that much cannot be expected in the washing waters. It is possible that you have been adding too much salt, as chloride of silver is, to some extent, soluble in a solution of chloride of sodium, and you may have been re-dissolving the small quantity that was precipitated. Hydrochloric acid will also act as a solvent if used in excess.

**EXISTING COPYRIGHT.**—Can you tell me whether the original of the enclosed is copyright, or whether I shall be free to publish as postcards, and also whether I can copyright the enclosed?—  
F. H. H.

We cannot say for certain whether the copyright in the original has expired or not. But from the age of the picture we should think it had. The copyright in a picture endures for the lifetime of the artist or engraver, and for seven years after his death. You can, of course, register the copyright in your reproduction, supposing there is none in the original. But anyone else will be able to make copies from the original picture.

**BLANCHARD'S PAPER.**—Could you very kindly tell me if anyone now owns the business once carried on by Mr. Valentine Blanchard, of Shepherd's Bush, and, if so, his name? Failing this, can you kindly give me any information, or where I could obtain it, as to Mr. Blanchard's "Platino Black process"?—F. ORAM.

Mr. Valentine Blanchard has been dead many years now, and his paper business is not being carried on by anyone. So far as we are aware, Mr. Blanchard did not publish the method by which it was prepared. However, very similar results may be obtained on the modern platino-matt papers.

**CELLULOID FACED PICTURES.**—Will you please reply to the following: 1. Can you tell me how miniatures (cheap) are prepared and coloured with celluloid fronts? I wish to do them but do not know where to get the celluloid. 2. Is there a list of photo-

graphers in the United Kingdom published from which wholesale houses obtain names and addresses for circularising, etc.?—Focus.

1. The prints are tinted with aniline dyes, which may be had from any of the dealers. The celluloid may be had, in wholesale quantities, from Messrs. Guitemann and Co., 35, Aldermanbury, E.C. The method of applying it may be learnt from a pamphlet published by Fallowfield's, who supply the necessary appliances for the purpose. They probably also supply the celluloid in retail quantities. 2. Not that we are aware of.

**ANACHROMATIC LENSES.**—I would be glad if you could tell me where I could obtain full details of price, etc., of the new French anachromatic lenses, and if there is an English agent for the same.—W. F. TAYLOR.

Two French makers of the anachromat lenses are M. Turillon, 122, Rue Gravel, Paris, and M. Morin, Ligny-en-Barrois, Meuse, France. We believe Messrs. Staley, Thavies Inn, London, E.C., are acting as agents for one or other of these firms. We would also refer you to Mr. F. C. Clarkson, Colchester, who is agent for the French Hermagis lens, giving results very similar to the anachromats. You will see specimens of these latter at the present exhibition of the Royal Photographic Society.

**FRANK BUTLER.**—1. They do. 2. Yes, proprietorship or management of a photographic establishment.

**COPYRIGHT (Aberdeen).**—1. You were decidedly wrong in supplying the print without the sanction of the one for whom the photograph was taken. But as the copyright in it was not registered, we do not see that you can be proceeded against under the Copyright Act. 2. Under common law we should say that proceedings can be taken for damages, if any can be proved. We should advise you to wait until process is issued; if it is, then state the facts to your solicitor. If the one for whom you did the photograph registers the copyright in it, he can restrain further publication of the postcard if he thinks proper, and you from selling further copies of it.

**E. FOX.**—The spots are undoubtedly due to metallic particles, most likely iron. You should look to your water supply and filter the water you use by trying a double thickness of thick flannel over the tap.

**C. H. MADDEN.**—You do not state in what order you print; it is advisable to put the red impression down first. Slow transfer of the dye is due either to too little ammonia in the red solution or insufficient soaking of the transfer paper. It can be considerably facilitated by soaking the transfer paper in water at 70 deg. Fahr. If you are still unsuccessful and care to send up a set of print plates and a failure, we will have some trials made for you. Are you sure your red printing plate is not over exposed?

**STARTING IN BUSINESS.**—I have an ambition to go into business as a photographer, but at the present time I am a clerk (married) at a salary of 30s. per week. For the last ten years, however, I have carried on photography in my spare time as a "professional-amateur," and during that time have gained a good amount of experience, and have done fairly well. At the present time I have about £20 in hand, and have thought (as this is a military town with a population of 40,000, with ten photographers) that I might be able to get on. If you thought I might try my luck would it be better for me to take a shop and build studio at rear, or have a private house with showcase in front? I believe I possess all the apparatus I should require, but as it is a question that wants a little consideration, I thought you would not mind giving me the benefit of your experience upon the matter, and whether I should stand a chance.—"HYPO."

Yours is a rather strange question for us to answer. One would think you could answer it better than anyone else could. You say that you are getting thirty shillings a week, and "doing fairly well as a professional amateur." It is for you to consider whether it would be well to throw this up, and with the small capital of twenty pounds, out of which you will have to build a studio, provide show cases, etc., attempt to compete with ten established photographers in a place of only forty thousand inhabitants. We think the matter should receive careful consideration before you make the attempt.

**P. MARTIN.**—The only work on the subject is contained in "Zur Photochemie und Spectralanalyse," Part V., by E. Valenta, which is in the R.P.S. library. The object of precipitation is to produce a pigment; therefore it would be useless for your purpose. You do not state the colour you want, but the pinatype dyes should answer your purpose, and stand at least eight months' sunshine.

**STAIN.**—We could have advised you better had you sent us a negative to look at. The stain may be dichroic fog, in which case a solution of potassium cyanide, 5 grains; sodium carbonate, 20 grains; water, 2 ozs., would remove it. If this does not, it would be as well to try some of the clearing solutions on p. 955 of the "Almanac."

**G. FRANK.**—Try the outfit of Messrs. Sichel mentioned on p. 955, and write us again if it does not suit your requirements.

**H. E. C.**—(1) We believe he holds a professional position. (2) I think they do not.

**ARTISTIC.**—We know of no work dealing practically with the subject.

**H.R.H. THE PRINCE OF WALES** has sent Sir William Trevelyan as a donation to his "Crippled Children's Fund." The fund for special reasons been opened much earlier than usual, and His Majesty the King, as has already been stated, has an annual subscription of ten guineas. The object of the fund is to hamper of Christmas fare direct to every crippled child who cannot attend the annual children's banquet at the Crystal Palace. On an average 7,000 hampers are thus despatched every Christmas, each containing enough to enable the child to act as hostess for his family for the day. Subscriptions should be sent to Mr. Alfred William Treloar, 69, Ludgate Hill, E.C., who has now a scheme going for thirteen years.

**MESSRS. ERDMANN AND SCHANZ** have moved to more convenient premises not far from their previous house. Their present address is 109, Bedford Hill, Balham, London, S.W.

**BIRMINGHAM Bankruptcy.**—The further proceedings of the examination of Mr. J. A. Draycott took place at the Birmingham County Court last week, before Mr. Registrar Whitlock. A deficiency of J. A. Draycott is put at £1,790, and the Official Receiver drew attention to the fact that at a previous examination he had disclosed the whole of his liabilities. The debtor: "No, sir. Why did you not disclose £150 judgment obtained against me by your wife under a separation deed?—I had arranged that it should not be pressed. Was there any such arrangement?" "It was not put into form, but it was between us. Debtor further stated that he had paid her £3 since the date of the receiving order. The Official Receiver said the judgment was for arrears on a deed of separation which debtor was to pay £2 per week. The debtor: "I paid it." The examination was adjourned until October 25 for further matters to be amended.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY

Exhibition of photographs by members of the Professional Photographers' Association opened yesterday, Thursday, at the "British Journal" office, and will remain open until Nov. 10, from 10.30 to 4.30 (Saturdays, 10.30 to 12.30). We publish an article on photographs by F. C. Tilney. (P. 805.)

Notes for short studios. Some notes for the inexperienced ap-  
p. p. 804.

Photographers troubled with fraudulent canvassers should invoke  
aid of the local newspapers. (P. 802.)

Mercury Vapour Lamp.—Some hints on portraiture by this  
artificial light appear on page 808.

Daily paper assures us that boot-button photographs are to be  
fashion. (P. 803.)

The Croydon Camera Club last week a demonstration of  
the new platinotype paper, was given by Mr. W. H. Smith.  
(P. 807.)

Pyro-soda Developing Solutions.—We publish some corre-  
spondence confirming our previous notes on this subject, and em-  
phasising the fact that the soda sulphite and carbonate should be  
used in separate solutions. (P. 816.)

Photographic journal in Esperanto has been published. (P. 802.)

The Correspondence Columns.—Photographic research: the  
Ozobrome Process: Direct Bleach-out Colour Photography: and  
of Production. (P. 816.)

The Bristol Camera Club have held their first, and a very suc-  
cessful, exhibition. (P. 811.)

We publish an account of the work of F. Benedict Herzog, whose  
pictures at the Salon have been greatly admired. (P. 809.)

Method of toning prints by chemical means, supplemented by  
the new patented. New "Cooke" lenses are among other  
items of the week. (P. 811.)

## EX CATHEDRA.

### The Pyro- Soda Developer.

Our notes on this subject, and on the stability of soda sulphite in conjunction with alkali, seem to have aroused much interest. Our experiences do not appear to have been on all fours with Mr. Bennett's, as described in his article and in his letter on page 798, but we have tested the matter for such a long period that we must hold to our opinion that pyro is preserved more effectually by neutralised sulphite than by metabisulphite, and that sulphite rapidly deteriorates in conjunction with an alkali. This latter effect is very marked with the neutralised sulphite solution, for while the addition of alkali causes it to rapidly deteriorate, yet in the neutral state it keeps almost indefinitely. In saying this we are gauging keeping qualities solely by the behaviour of the solution with developers such as pyro, amidol, and hydroquinone—chemical tests will come later. Our experiences with the neutralised sulphite solution date back for three or four years, but in regard to the use of metabisulphite and other preservatives we have been experimenting and comparing formulæ for at least thirteen years. In the days of pyro-ammonia we used the very popular ten per cent. pyro stock solution containing ten per cent of metabisulphite, or twice the quantity used by Mr. Bennett. This we found to be a most wasteful and deceptive formula, for the developing power of the solution deteriorated rapidly within a few days after mixing. There was a marked difference in the behaviour of a quite fresh solution and one a fortnight old, but it appeared that the rate of deterioration was most rapid in the first few days and then fell off. In a month or two the solution became very unsatisfactory. It would continue to develop for many months, but there was an increasing difficulty in obtaining density, and the net result was that in a few years fully a pound of pyro must have gone down the sink pipe in spoilt pyro solution. One source of trouble with this solution was the free sulphurous acid which increased in quantity as time went on and neutralised more and more of the alkali. This effect is not of so much importance with the pyro-soda developer, but it still takes place, and we are strongly inclined to suspect that Mr. Bennett's success with his own formula depends more or less on this free sulphurous acid which helps to compensate the deficiency of sulphite in his alkali solution. It must also be observed that as he uses more sulphite than we did in our combined alkali and sulphite solution the effect of deterioration (as regards stain) is not likely to be felt so rapidly. Moreover, a loss of developing power in his pyro solution may be counteracted by a loss of restraining power in the alkali solution, due to the diminution of sulphite, and so may escape notice. Our experience shows that the traps and pitfalls for the investigator are innumerable in this matter of development.

**Matters for Investigation.** Our notes up to the present embody all the practical results we have arrived at. We felt they were worth publishing, as it was most evident that we had found an extremely useful and economical formula. There are, however, many points that require elucidation, and we hope to take these up shortly. Mr. Bennett's article and letter are both valuable, as they suggest a course of comparative experiments. For instance, it will be noted that his formula contains bromide while ours has none, and that it contains apparently about the same amount of sulphite. Yet, unless his developer is a remarkably slow one, ours must be as much restrained as his, for its one defect is its slowness. If Mr. Bennett would kindly give us an exact formula for a developer containing a definite number of grains of pyro to the ounce, and also some idea of the time taken to attain average density, and of the number of plates that can be developed in succession without stain he would greatly assist us. There is a mystery about the extraordinary restraint exercised in our developer that it is most desirable to solve, for it is an action of a most useful kind, and one that should be of great value if it can be controlled. The relative keeping qualities of the solutions should also be compared by keeping them side by side. Another point that we hope to study is the constitution of stale sulphite solution. Mr. Bennett, like many others, seems to attribute all its deficiencies to the presence of sulphate, but as a matter of fact we have found that a stale sulphite solution and a sulphate solution behave altogether differently in combination with developers. This seems to be a very weak point in most theories concerning the action of developers. In spite of all that has been written on the subject it does not appear that anyone knows what happens or what exists in the complex mixtures of sulphites, bisulphites, metabisulphites, alkalis, and sulphates that help to form the average pyro-soda developer. There are many possibilities that do not seem to have been tested. That different conditions exist seems to us to be amply proved by the results of our initial experiments, but it may take many months to strictly prove that point, or to gain even an idea as to what those different conditions are.

#### Foto-Revuo Kun Ilustraĵoj.

Of course, our readers will easily see what that means. It speaks for itself quite plainly. We trust that nobody will conclude that our compositor and proof-reader have been "over the way" together, and stopped too long. We are truly proud to flourish this utterance from the new Tower of Babel, for it signifies that photography, youngest and sprightliest of artistic sciences, is in the forefront

of fashion, the first of them all to have a journal of herself in the serio-comic language, yclept "Esperanto." We must not be hard on the lingo because it is so full of smiles and tears. It has been designed, no doubt, to view to flattering the vanity of every existing journal under the sun by making each one think that its journal is the largest. On this assumption Dutch and English seem to score, for a general shake up and reshuffle of these two would make very passable Esperanto, too. But when all is said and done, we should like to know who is going to read their photographic literature "allsorts mixture"? Here are some developers: pirogajla, Hidrokinono, Glicino, Amidolo, Metolo. The idea is that if in a foreign country one asked for garlic or something would be offered, but at the same time Metolo the shopkeeper would lean across the counter to embrace the customer, shedding fraternal tears of joy whilst he handed out the article. Vivaj Esperanto! Fotogramatoroj and professionaloj! The Foto-Revuo is published monthly in Paris, and the subscription price is five frankoj.

#### How to Fight the Canvassing Fraud.

A correspondent in the provinces writes with reference to a recent visit of a fraudulent canvasser to his town. The method was a localised edition of the plan adopted by that great benefactor of his race, Tanqueray, of Paris, namely, to offer an enlargement of a photograph for nothing and extract an exorbitant payment for a copy. Our friend promptly placed a statement of the doings of such gentry before the editor of the local paper, and sent it with cuttings from our own pages on the subject of canvassing roguery. We give the comment of the paper, and advise all of our country readers to take similar measures in the event of a visit from the canvassers:—"I should like to draw the attention of readers to certain persons who are said to be paying attention to certain Shropshire towns at present, soliciting orders for photographs, at what looks upon the face of it a very reasonable price. But there is a condition attached to the purchase. The sitter must buy the portrait framed, and it is in the quality of the frame that the man gets his pound-and-a-half of flesh. Another of these free lances of the profession is to secure orders for photographs by using the name of a well-known photographer. Money is demanded as a deposit on an order. In some cases the people are asked to visit a studio; in others they are told they will be waited on and invited "to moisten the lips a little" in their homes. In both cases the object is the same—in

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1907.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-sixth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of 1,616 pages, and the entire edition of 25,000 copies was sold out before publication. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1907 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

THREE-COLOUR PHOTOGRAPHIC PRINTING PROCESSES, and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1907 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1907 will appeal to photographers all over the world as a daily reference guide in practical photography. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, features of an informative nature will be added.

**\*\* IMPORTANT NOTICE.**—Our publishers ask us to draw the attention of advertisers to the fact that the latest date for receiving orders and copy for advertisement in the "Almanac" is THURSDAY, OCTOBER 18.

the canvasser may "moisten his own lips" in another position at their expense; for neither the deposits nor the canvasser are heard of any more."

\* \* \*

We have learnt to expect great things of Mr. Stieglitz' publications, and yet each new number charms us with its demonstration of what a photographic journal may be under the control of a man possessing infinite patience and the artistic temperament. The present issue is adorned with plates by Demachy, Puyo, and Le Begue, the French giants any one of whom would secure its success. There are articles too, and the most important one by Demachy on his experience and practice with oil painting. It is written, of course, in M. Demachy's wonderfully lucid and idiomatic English. Similar epithets cannot be applied to the English of Mr. J. T. Keiley, who writes upon Vanity. The pellucid ease and grace of his writing may be judged from this:—"Vanity makes vulnerable the weakness of smallmindedness, natures naturally simple and large, and generous of thought." We fear we are not as many subscribers to "Camera Work" as this country as it deserves. One or two societies, however, chase it, but many others would do well to follow their example if they wish to let their members see what the pictorial work is like. They can take it from us, for the reproductions Mr. Stieglitz gives them are as true to the originals as they can be made, and, in many instances, are indistinguishable from them. "Camera Work" is published by Mr. Stieglitz, at 1,111 Madison Avenue, New York.

\* \* \*

We glean from the "Evening News" that "the latest thing in footwear is a pair of boots, inside the buttons of which are inserted small photographs of either the owner or his friends." There is an ambiguity about the last portion of the announcement that may signify that the photographs are so indifferently done as to be as much like the owner as the boots as like his friends. This being so, it is difficult to see exactly where the great advantage of the invention comes in. If these photographs are not for purposes of identification, what are they for? As mere ornaments they would miss fire with all but the most myopic-eyed, for a little splash of mud would look as pretty on a boot-button at a range of, say, five feet six. A photograph on the fair and heaving bosom of an *ingénue* might be worth the closest possible inspection; but the photographs are rare when a man is so near a lady's feet as to recognise a portrait in her boot-buttons. Supposing that the idea is identification of boots by their owner, however, identification of their owner by the police in cases of theft or what not, then it is positively essential that the photograph resemble the owner and not his friends.

\* \* \*

The exceptionally hot and dry summer which we have had has, no doubt, had its effect on the roofs of many photographers' studios, causing the putty to become abnormally hard and brittle, with the result that it has cracked away from the glass, and thus will let water in with a heavy down. Nothing looks much worse in a photographic studio than stained blinds and curtains. Costly backgrounds, too, are frequently spoilt by rain finding its way through the roof. We may direct attention to the fact that the present is an excellent time to see the roof and have made water-tight for the winter. In many cases a couple of coats of good white lead paint, carefully applied, will do all that is necessary. In others, however, if the

putty has cracked away from the sash-bars, it should be chipped out, a thin coat of paint laid on, and fresh putty applied. The work should then be repainted with two coats of paint made with good raw linseed oil. If this be done at once, it can be more effectually done than is possible later on. Modern studios, as a rule, are not so very troublesome to keep watertight, as they contain far less glass than the old-fashioned "glass-house" studio; still, their roofs require periodical attention if stained blinds, etc., are to be avoided, and now is the time to put the work in hand.

#### LENSES FOR SHORT STUDIOS.

THERE is little question that at the present time there are many studios in which it is impossible to produce really good pictures. Those who regularly read through the "Answers to Correspondents" column of this journal cannot have failed to notice the number of questions we have answered with regard to the arrangement of windows, blinds, and the light in short studios—eighteen, sixteen, and one this week only twelve feet long. A short studio means the employment of short focus lenses, and short focus lenses mean that the camera must be placed nearer to the sitter than is desirable to get pleasing perspective in portraiture. Most people know quite well that by the use of wide-angle lenses in outdoor work—say for architectural subjects in confined situations—violent perspective is produced, which is very unpleasant in the pictures. But many do not seem to realise that the same conditions obtain when a short focus lens is used in the studio and the camera planted very near the sitter. Although the effect may not be quite so immediately conspicuous as it is in the case of the interior of a building, it exists nevertheless, and the portrait is an unpleasing one, though the sitter may not be able to say why, and the photographer in many instances be ignorant of the cause. In some cases short studios are necessitated by want of space to build larger, sometimes by the exigencies of the building laws, and sometimes by false economy. Some of the inconvenience of a short studio may, at times, be overcome by having a means of placing the camera outside—say, by having a door at the end so that it can be taken into the garden, or perhaps into another room.

Reverting to the article on lenses for studio work (see page 764 *ante*) we shall now consider the question of short studios. We may at once say that it is a mistake to build studios in which lenses cannot be used of such focal length as will yield pleasing perspective. But there are circumstances in which, by reason of the exigencies of building laws, or limitations of space at command, a longer studio cannot be erected: it is a question of a short one or none at all. In some instances, with a desire of saving outlay, a studio is made shorter than it need be—an act of false economy when the best possible results are of first consideration. Nevertheless we shall doubtless be consulting the wishes of many of our less experienced readers by giving some words of advice on the selection of a lens for such studios as they are compelled to work in.

In the previous article it was mentioned as generally recognised that in order to get pleasing perspective in portraits the focal length of the lens used should be at least double the longest dimension of the picture. This rule was laid down by eminent authorities in the days when full length cartes and cabinets were so much in vogue, and the lenses recommended were, for the former, about eight and a-half inches, and for the latter eleven to twelve inches focus. With either of these from eighteen to

twenty feet between the camera and the sitter is required. It is by reason of this distance that the perspective in the pictures is so satisfactory. In the United States greater attention seems to be given to this point than is the case here, for we see from the price list recently issued by one of the leading opticians there that twelve-inch focus lens are not recommended for the cabinet size, except in galleries of limited length. The sixteen inches focus, says the prospectus, is the regular cabinet lens as giving the best pictorial results, and it will also do for 10 x 8 plates. This lens requires some five-and-twenty feet between it and the sitter, and, of course, necessitates a studio longer than many photographers possess. We may here say that we do not consider so great a distance as this desirable in this country, particularly in large towns where the atmosphere is usually more or less hazy, inasmuch as the intervening haze has a tendency to make the negatives flat or lacking in brilliancy.

The mistake is frequently committed by portraitists of limited experience of trying to make one lens serve for all purposes—full length cartes, cabinets, and groups, as well as three-quarter lengths and large heads. In a short studio this necessitates a short focus lens to take the full lengths, and if that be used for the portraits on the larger scale the perspective will be very violent, and so-called "distortion" evident. It is, no doubt, within the knowledge of many workers under these conditions that their large heads do not give the same satisfaction to their sitters as do the three-quarter and full lengths, although the sitters do not find any special fault with them. The pictures are sharp and otherwise good photographs, yet still they are not satisfactory, and few re-orders are received. No experienced photographer thinks of using a very wide angle lens for outdoor work if one of ordinary angle will include what is desired, because of the violent perspective, owing to the closeness of the camera to the subject. The same conditions prevail when the camera is brought close to the sitter in the studio, though this fact is often overlooked.

Large heads, taken direct, have never met with much favour in this country, though they are very popular on the Continent; by large heads we allude to those of about four or four and a-half inches from the top of the head to the point of the chin. The reason for this is, no doubt, that abroad much longer focus lenses are used for the work than is the case here, so that there is a greater distance between the camera and the subject, and the perspective is good. Many of our older readers will well remember the pictures that were shown in the Crawshaw competition for the prizes offered many years ago for the best life-size portraits taken direct, and the comments that were made upon them, alike by the photographic and the lay Press, some going so far as to term them "abor-

tions"—and, in fact, they were little better than that. Their defects were due to the camera having to be so close to the subjects. The lenses used for the pictures were something about thirty-six to thirty-eight inches focus. Consequently the cameras had to be approached to six feet of the sitter—no wonder at the violent perspective distortion and the severe criticisms. Similar defects are produced when large heads for, say, cabinet pictures are taken with the camera only six feet or less from the sitter, though they may not, at first sight, be so plain as with the life-size heads.

One of the mistakes frequently made by novices is of being guided by opticians' catalogues. Lenses are recommended to cover certain size plates, which those of the makers do admirably, and the inexperienced select one or use it for the full size, quite regardless as to the perspective it gives when so used. For example, what is recommended by the different makers the No. 3 cabinet, or some "3 B," which is of from eleven to twelve inches focus, and is generally used for that size picture, will really cover the whole plate when placed near the sitter, though only recommended for the smaller size. If used for full size it will cover, the perspective must be much less unpleasant as compared with that in the smaller sizes.

Having said this much, the question comes as to most suitable lenses for short studios. Portrait lenses of the Petzval type are the most rapid, and therefore best for studio work. They are made of so short a focus that they require but twelve or thirteen feet between the camera and the sitter, and they are the best to use for full length portraits and groups in a studio that will not permit of longer focus one being employed. But they will not do for full length cartes, as they would require a distance of about eighteen feet, so that for cartes and smaller sizes a shorter focus instrument is necessary. The large format may be used for cartes, three-quarter length or head and bust, but the smaller will not do for cabinets. The large format again, are not suitable for cabinet head and busts, but the camera would have to be placed very near to the subject with the result already referred to. If pictures on a smaller scale are to be produced—say head and bust—then a lens of larger focus should be employed, so that whatever distance is required from twelve to fifteen feet intervenes between camera and subject. Under this condition satisfactory results may be obtained even in a short studio. I mean, of course, that those who have studios of small dimensions should have a larger supply of lenses than is necessary with those who possess larger ones in order to secure the same satisfactory pictures. In conclusion I would recommend that, in either long or short studios, the longest focus lens, within reasonable limits, that can be worked should be used in order to produce the most pleasing pictures.

**BOARDMAN Arc Lamps at the R.P.S. Exhibition.**—Messrs. W. Watson and Sons ask us to intimate to professional photographers that their representative attends daily at the R.P.S. Exhibition, and demonstrations of the Boardman electric studio light can be given to anyone interested. The demonstration would be sufficient to show the satisfactory nature of the light and the ease with which soft portraits can be obtained.

**DRYING Velox Prints.**—A correspondent of the "Camera" describes the following method used in an American factory: A piece of mailing board showing the corrugating on one side, the other smooth, is used, and the smooth side coated with shellac and dried so as to remove the impurities. A piece of loose cheese cloth is then laid on the prepared board loosely, and then the prints laid face down on the cheese cloth. Blotting paper is then placed over the back of the prints, and the strip, which may be 5ft. to 10ft. long, is rolled up, but not too tight. String is placed around

the roll top and bottom, and it is then placed in an oven or over a stove. Prints come out perfectly flat and dry in a very short time—in fact, about one-eighth the time usually occupied in drying. The corrugated surface allows the warm air to circulate through the entire roll—in fact, to a degree, it is on the plan of the developing apron used on the developing machine, only in a different form.

**PHOTOGRAPHS in Catalogues.**—According to leading tradesmen interviewed in the "Daily Express," photographic catalogues are the draper's autumn novelty. The latest shoe photographs are of a pretty foot or a twenty-button length glove on a well-shaped arm and make a far more effective picture than if sketched. Rare embroideries and priceless laces arranged on a dark ground are more picturesque when depicted by a camera than by an etching pen. "We photograph gloves, laces, curtains, ornaments, and umbrellas," Messrs. Whiteley's manager says, "but gowns and hats are always sketched."

# THE EXHIBITION OF PHOTOGRAPHS BY MEMBERS OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

## AN ARTIST'S VIEW.

YESTERDAY the Editors opened to the public the doors of their little gallery, where, for the first time in the history of the calling, the professional photograph of commerce is exhibited where the amateur is excluded. On the whole, perhaps, the amateur does not suffer by remembered comparisons. That is strictly on the whole, however, for when particular cases are dealt with the amateur does not score by any means. There is a masterly slickness about professional work that is not out-balanced by the "temperament" and "feeling" of his rival who pays no rent and taxes for his studio. We miss here our old friends, fuzziness and obscurity. We do not see faces shown as though they were looking through a small hole in a shutter that had been fitted with a magnifying glass. All here is decorous, clean, and of bright tone. Men and women appear as they are—when they go to the photographer's.

If only the amateur and the professional—the best of both—could be rolled into one, what a fine thing camera portraiture would be! In one or two cases where this state of things has happily come about the results are, indeed, fine things. But as a rule the professional is too hedged about by an unpurified popular taste to be able to let himself go, even if he would; whilst the amateur continues to let himself go to lengths that certainly get him talked about. What kind of talk it is he does not mind in the least.

To be just, it must be admitted that all the modern improvements and developments that push affairs forward upon artistic lines are seized hot from the hands of the amateur. The professional, however, uses where the amateur frequently abuses. Particularly is this noticeable in the case of mounting. Even the multiple mount has been taken over by the professional. On the other hand, the amateur does not seem to borrow from the professional. It is doubtful whether those very neat and taking Cosway mounts, so full of an old-world grace, will ever be used by other than the class for whom they have been made. They are certainly a great help to the likenesses of dainty sitters, such as pretty women and children; but there is a danger of their becoming hackneyed when supplied from a maker wholesale. A safer and more artistic plan would be for each photographer to have his own borders designed by a good artist. They would then be associated with his work only, and a liberal selection would meet the demands of every class of work. In this connection, it cannot be too strongly urged that the designer should be trustworthy, if not of recognised ability; for a poor thing is positively damaging and infinitely worse than none at all. The hand-drawn miniature frame and ribbon design round the pretty head that is numbered 66 in the exhibition is only good, though not new, in idea. It is so feebly designed and so childishly drawn as to spoil the fine work it is supposed to embellish. Comparing this with a simple double line of light grey ruled round the print on a dark mount, as in No. 61, we see how far good taste may be removed from mere elaboration. Mounting is certainly not a strong point with the profession as a general rule. Many of the works exhibited here seem not to have caused their senders the shadow of a thought, for the prints seem simply stuck on to a card drawn out of a drawer where the bulk is kept for all purposes.

It is possible, of course, that some of the exhibitors have not regarded it as necessary to exhibit mounts to their brother workers, and have thus adopted a sort of temporary support in the shape of a piece of white card just sufficiently large. It is difficult otherwise to account for one or two really striking works so meagrely furnished as they are.

Another point that shows weakness at times is the trimming of the prints. It is safe to say that a square thing is always unpleasant. If a lady at full length, with a long train thrown out across, occupies height and width to the proportions of a square, it is certainly better to sacrifice a little of the precious garment and get something approaching a panel shape than let the complete thing take the shape of a square. In the case of a court or theatrical dress that is the *raison d'être* of the photograph, care might be taken in posing to avoid a letter L composition. Many an instance is here of too much empty space on both sides of a figure. Settees and backgrounds are for their own sakes not worth the material they use up. All of them that is beyond the mere occasion of giving a physical support to body or hands can be pruned away with advantage. How much nicer would be the excellent "Queen of Spain," No. 4 here, if there were not so much space on either side of her to rob her of importance in the print! Other examples will be noticed by the visitor bearing out this principle.

Some specimens of tinted work are well worth inspection. One very full and elaborately coloured head and bust has been executed, so I understand, by the "Aerograph" air-brush. It is most cleverly done, and has a most charming effect. For the silky texture and sheen of white silk dress and shoes another relies upon body-white tastefully painted on a print of rather low tone. There is also a tinting of the flesh parts, as well as some unaccountable marks of colour upon the floor. A third is evidently tinted in imitation of a coloured mezzotint of a past century. There is much about it that is taking, and the background looks very like what it imitates; but the lighting of the little figure comes in such arbitrary patches that we should think a logical customer would want to know the reason why. Some lilies held in the hand are suppressed to the tone of the dark background. The subject that enjoys the hand-painted frame to which we have referred is likewise an attractively coloured print.

For artistic quality in purely photographic effects there are few things to surpass the beautiful back-view of a girl, No. 61. The softness of the flesh and hair, the lighting, and the general tone should be a pattern to many. Very pleasing, too, are some of the child subjects, one of which includes a pet lamb—surely not a property one either.

The posing of the figures is in all cases the matter least open to caviel. In some it is exceptionally good. This is, perhaps, a point that the photographer has been alive to the supreme importance of, and has, therefore, given it more study and cultivation than other matters not so obviously essential. We trust that by this and possible further exhibitions those who are wanting in certain matters will find here the wherewithal to fill their deficiencies, though what the first-class men are to find except mere gratification it is hard to see.

F. C. TILNEY.

## THE EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY

To the notices which have appeared in the past two issues of the "Journal," an addendum must be made in reference to two exhibits which we omitted to include when dealing with the sections to which they properly belong. These are the displays of Messrs. Elliott and Sons, of Barnet, and of Mr. Adolph Langfrier. The former, which is one of the large trade exhibits, is placed in the "professional" room, and the latter, from exigencies of space in this same south room, is shown among the trade exhibits in the north room. Hence, as our notices of the two sections were in different hands, the exhibit in each not belonging to its department, was passed over, and the oversight, we regret to say, was not noticed until too late to remedy it in our last issue.

Messrs. Elliott, we would now point out, occupy the whole of one wall in the south room with prints on their bromide papers. They set apart a section to toned prints, and show the results of the sulphide process (Barnet "Owl" toner) on the various classes of their paper, such as "Tiger Tongue" (white and cream), rough and smooth, ordinary and cream crayon. The collection includes an immense variety of portraits, and scapes and seascapes, and while it is a very strong argument for the bromide process is the best evidence of the

perfection to which Messrs. Elliott have brought the manufacture of their papers. The big enlargement of a figure study by Mr. Cr. Richards is beautifully soft in its tones, whilst the wide range of gradation in some of the architectural subjects is equally remarkable. Extremes of this kind are a severe test of a paper, and any one studying the collection can see how well the Barnet paper comes out of it. Most of the negatives are on "Barnet" ortho plates, and those interested in orthochromatic work will discover some beautiful examples on the wall—not the most conspicuous perhaps, but having tone-rendering which is extremely good. The "Surrey Wood," N in the little "Barnet" catalogue, is a charming example.

In the north room Mr. Adolph Langfrier has crowded his space with what he calls "every-day portraiture." We can have too many of the best, and for purposes of display alone half the number of portraits would have been better. Yet the large number has not meant inclusion of a good deal of bad work, and if this be Mr. Langfrier's everyday photography we congratulate him upon it.

His portraits of men are strong and life-like—see those of Mr. Humphrey, McIntosh, Manly and Bridge—and women he can take as lightly and delicately. He has some very pretty figure studies. His mounting and framing we admire in almost every case.

## INTERFERENCE BANDS, GRAPHIC OPTICS, AND SENSITOMETRY AT THE R.P.S.

THE opening meeting of the Royal Photographic Society took place on Tuesday last, but owing to the continued illness of the President, Major General Waterhouse, the presidential address had to be omitted from the proceedings. In place instead, a symposium of science was provided by Messrs. C. Welborne Piper, E. J. Wall, and C. E. K. Mees. Mr. Piper explained the model illustrating optical systems, to which a medal has been awarded in the present exhibition.

Mr. E. J. Wall dealt with the Lippmann photographs exhibited by Mr. E. Senior in the technical section of the exhibition. The exhibit, he said, was described in the catalogue as a "Lippmann photograph produced by exposing film successively to two continuous spectrums, the red end of one being superposed on the blue end of the other. Two

means a new hypothesis or theory, but only a necessary sequence of the generally accepted ideas."

Neuhaus at first called them Talbot's interference lines, but Talbot pointed out that interference lines would be seen, when examining a spectrum, if a thin sheet of mica was passed along the spectrum from the violet end till half the pupil of the eye was covered. The rays passing through the mica were retarded and caused these in-

Fig. 1.

short spectra are thus obtained crossed by fine dark lines first observed by Dr. Neuhaus.<sup>1</sup> The concluding words of this description might or might not be correct.

These lines might be either due to the use of gelatine plates, or they might be true interference lines. The former were obtained in trying to produce the latter, which, according to Dr. Neuhaus,<sup>1</sup> would be most easily obtained on albumen plates, as the latter have a more even film.

If these were interference lines then they should be called Zenker's lines, because he was the first, Mr. Wall believed, to point out the possibility of their formation, for he says,<sup>2</sup> "although the formation of stationary waves by two rays of similar wave length meeting one another has not yet been experimentally proved, yet it is by no

Fig. 2.

ference lines with the light that did not pass through the mica. Later, he seemed to have suggested that they should be called Zenker's lines.

If they were the latter, then Neuhaus was not the first to observe them, for he states that "to his knowledge Valentia first prepared similar photographs at Dr. Zenker's suggestion three years previously. Neuhaus has made several experiments, such as bleaching the first spectrum and then superposing the second, and so on.

<sup>1</sup> Die Farben photographie nach Lippmann's Verfahren, 1893, p. 54.  
<sup>2</sup> Lehrbuch der Photochromie, 1895, p. 80, also Dr. Schwalbers edition, 1900, p. 121.

This subject, continued Mr. Wall, had been treated at great length by Dr. Pfaunder, of Graz<sup>3</sup>, and more briefly,<sup>4</sup> and from the latter the following extracts may be of interest, as they explain very clearly the formation of these dark lines, and are proof of the correctness of Zenker's statement above.

"Fig. 1 shows two parallel but reversed spectra. The upper and lower parts correspond to each of the two spectra, whilst the middle portion represents the overlapping parts. The latter shows here two similar colours are superposed, one pair of dark sharp stripes, and on each side of the same others which are fainter and less sharp at equal intervals. The colour in the middle is a bright indigo. Towards the ends the colours are less bright and correspond to mixtures, where the bright green, the yellow, and especially the red, are in preponderance. At the extreme ends the H lines are visible."

"Fig. 2 is still more instructive. This shows a diagrammatic sketch of two spectra crossing at right angles. Here the dark stripes appear near the diagonal R S, and their intensity and sharpness increases towards the corners V V'. Along R S are found, as is obvious, the pure spectrum colours; towards the corners V V' are the dampened compound colours, in which the bright yellow and red overpower the other colours. The diagram corresponds to the results which must be formed with a diffraction spectrum. With prismatic spectra theory requires a faint curvature of the lines outwards, which, as a matter of fact, is to be seen in the original. According to Dr. Neuhaus's suggestion I have called these lines Zenker's stripes."

This diagram explains the "dark lines on the back, traversing the image obliquely" in Mr. Senior's No. 5 exhibit.

<sup>3</sup> Über die dunklen streifen, welche sich auf den nach Lippmann's Verfahren dargestellten Photographien sich überdeckender Spektren Zeigen (Zenker's Zeitschr. d. Naturforsch. Ges. Wien. Vol. 63. Jan. 1904.

<sup>4</sup> Eder's Jahrbuch, 1904, p. 329.

Dr. Pfaunder then says: "Quite apart from the theory of their formation these images prove the important fact that with a large number of pairs of colours their superposition on a Lippmann photograph does not reproduce the physiological colours, but causes a destruction or weakening of the light."

The greater the difference in wave length the less these periodic changes are produced, and with indigo and yellow are scarcely noticeable. The mixture of the spectrum rays caused by the reversal of the spectra can be at once traced along the dotted horizontal and vertical lines.

Dr. Pfaunder, towards the end of his article, expresses himself very plainly, and says: "Lippmann's process, therefore, not only on account of its uncertain and difficult manipulation, but above all on account of its falling short of its theoretical basis, cannot be considered as a complete solution of the problem of photography in colours. . . . Lippmann's process will therefore always remain what it always was, an extremely charming and highly interesting physical experiment."

Mr C. E. Kenneth Mees explained the apparatus of his design. He made and exhibited in the New Gallery by Adam Hilger. The first was a modified Hüfner spectrophotometer, fitted with a device (in addition to the spectroscopic) for dividing up the beam of light into two parts, the upper one passing through the substance to be measured, and the lower one through a polarising Nicol. The beams are then brought into juxtaposition and pass through an analysing Nicol mounted on a divided circle, by turning which the gradual extinction of the polarised beam can be accomplished.

He also explained the use of the gradation photometer already described in our pages when reviewing the technical section of the exhibition.

## JAPINE PLATINOTYPE PAPERS.

The opening night of the Croydon Camera Club, on Wednesday the 11th inst., brought a full attendance of members to hear the President, Mr. W. H. Smith, explain the properties and method of working of the latest product of the Platinotype Company. Inasmuch as the Platinotype is authoritative, and the Platinotype papers have attracted a considerable amount of attention, a full abstract of Mr. Smith's remarks may be useful to many.

### What is Japine?

was the question often propounded, Mr. Smith said. Many photographers taking it to be a new paper having no relation whatever to platinotype. As a matter of fact, the Japine printing papers are pure platinotypes, made in "sepia" only, and in two qualities, one with a semi-matt or "egg-shell" surface, the other being glossy, but not very glossy, the latter having something of the characteristic appearance of a sepia print whilst wet. Many users in the past had expressed a wish that a paper might be made to retain the fine and lustrous appearance which sepia platinotype papers presented whilst lying in the baths, and in response to such demand a paper fulfilling this condition to a great extent had been introduced a few months ago by the company. The semi-matt Japine paper gives a slightly warmer tone than the "ordinary sepia"; the glossy, much warmer tones than the semi-matt. The manipulation of both varieties is the same, and differs but little from the usual practice. Japine papers are not intended to displace the ordinary "sepia," but they may in certain cases give more pleasing results, according to the subject, quality, or character of the negative; whilst in other cases the ordinary "sepia" cannot be beaten, the employment of one or the other depending naturally upon the precise effect aimed at. Japine papers certainly afford more detail and greater shadow transparency. The typical negative suitable for platinotype generally, viz., a somewhat soft one, and full of gradation (not a flat negative), is equally applicable to the newer papers; these, moreover, possess a far greater latitude in printing than the ordinary black and sepia papers, and negatives generally considered too hard for the process under normal conditions can, with the Japine papers, be printed for the high-lights without choking, or burying the shadows to any noticeable extent.

It need hardly be pointed out that this is a very useful attribute. In addition, these papers will stand rougher treatment generally, and are not so easily affected by damp. In one or two instances in this connection, he (the lecturer) had kept Japine papers before printing for twenty-four hours exposed to a damp atmosphere in the dark, the only observable result being to slightly flatten the prints, without any alteration of colour. Workers in the United States had made trials on similar lines, which confirmed this statement. Mr. Smith then passed on to practically demonstrate the process, and showed some interesting variations obtainable in colour and contrast by alterations of the constituents of the developing baths, of which we extract so much as may be considered normal treatment or supplemental thereto.

### Printing

Storage calls for no special comment, the paper being kept dry in the familiar storage tubes of the company.

The precise depth to carry printing is the same as for the ordinary sepia platinotype. When the paper is being removed from the original tin, or from the storage tube, care must be taken, and in all subsequent operations, to avoid bending it sharply, or the surface owing to its nature, may crack. Only ordinary care is required to prevent this occurring.

### Developing,

Two formulæ are recommended, one containing special salts with a proportion of glycerine added; the other, a normal sepia developer. For general work the former is to be preferred as giving a normal amount of contrast from the average negative. The best temperature to employ is from 100 deg. to 120 deg. Fahr. Between these limits, which may be considered standard, little, if any, difference in colour can be noticed. Full development takes from two or three minutes, and to secure the richest tones full development is essential, but if a print has been inadvertently over-exposed it may be withdrawn at an earlier stage, and with prints from certain types of negatives, landscape subjects, for instance, there may be but slight loss in quality or colour, curtailing development, however, tended

to flatten the print. Several prints can be developed together in the same bath, being slid into the developer face up, with a fairly even motion, and then gently turned over. Working the bath below 100 deg. down to 80 deg. Fahr. results in proportionately colder tones, more contrast, and perhaps a slight loss of quality. It was somewhat of a paradox, but when this developer is used at a low temperature printing should not be carried so far. With the ordinary papers the case was reversed. If the temperature is allowed to exceed 120 deg. up to 160 deg. Fahr., more contrast than the normal is again obtained, with results generally disagreeable. Mr. Smith stated that in one experiment he had left a print in the developer for forty-eight hours; the print somewhat curiously gained in intensity, this being no doubt due to deposition of platinum on the image. The developer was an old one, and therefore contained a certain amount of platinum salt derived from former prints. The developer would keep fairly well if stored away from strong daylight, but a sharp look-out should be kept for any signs of deterioration of tone. Should this be observed a fresh bath must at once be made up. With the alternative formula (sepia salts) less contrast is obtained, a fact which may be taken advantage of when dealing with harsh negatives. The temperature of this bath should not be allowed to drop below 120 deg. or exceed 160 deg. Fahr. Within this range no appreciable difference in the character of the prints will be perceived.

#### Clearing and Washing.

These operations are carried out in the usual way, and call for no remarks, except that a little longer immersion in the baths than that prescribed will do no harm, and will at least be erring on the safe side.

#### Drying.

A preliminary bath of glycerine mentioned in the instructions, the lecturer said, was not essential, and it was perhaps better to omit it. The prints should be removed one by one from the last washing water, and after blotting off surface moisture, be laid face down

between layers of fluffless blotting paper, without further pressure than that afforded by the blotters themselves. The prints would dry flat.

#### Mounting.

Any good adhesive will answer, but Mr. Smith preferred the mounting process. It gives an added finish by no means despised. He here showed a capital little machine for the purpose very low in price, and successfully mounted a few prints on art paper to illustrate its simplicity of working.

#### A Warning.

The lecturer, in conclusion, warned his hearers against departing from the instructions issued by the company, the outcome of extensive experimental work. Variations in procedure, based on principles from a few isolated negatives, could never be relied on. Substituting developers of different constitution to those recommended might in some cases, and with some particular types of negatives, show differences, whilst in other cases, and under other conditions, differences might be most marked.
